<b>9</b>	<b>Frequently Asked Questions</b>	<b>123</b>
9.1	My rule is not getting any hits? . . . . .	123

9.2	I got hits, why didn't I get an alert? . . . . .	124
9.3	Why did I only get one alert when I expected to get several? . . . . .	124
9.4	How can I prevent duplicate alerts? . . . . .	124
9.5	How can I change what's in the alert? . . . . .	125
9.6	My alert only contains data for one event, how can I see more? . . . . .	125
9.7	How can I make the alert come at a certain time? . . . . .	126
9.8	I have lots of documents and it's really slow, how can I speed it up? . . . . .	126
9.9	Can I perform aggregations? . . . . .	127
9.10	I'm not using @timestamp, what do I do? . . . . .	127
9.11	I'm using flatline but I don't see any alerts . . . . .	127
9.12	How can I get a "resolve" event? . . . . .	127
9.13	Can I set a warning threshold? . . . . .	128
9.14	Does it support Elastic Cloud's "Cloud ID"? . . . . .	128
9.15	I need to go through an http(s) proxy to connect to Elasticsearch. Does ElastAlert 2 support it? . . . . .	128
9.16	About boolean value . . . . .	128
9.17	Is it possible to send an SNMP Trap with an alert notification? . . . . .	128
9.18	Is Email Alerter compatible with Microsoft 365 (formerly Office 365)? . . . . .	129
9.19	Does Email Alerter support the Google Gmail API? . . . . .	129
9.20	Can Email Alerter send emails via the Gmail sending server? . . . . .	129
9.21	Is it possible to send a JPEG image encoded as base64 in elasticsearch as an image attachment with an Email Alerter? . . . . .	129
9.22	Does the alert notification destination support Alertmanager? . . . . .	130
9.23	The es_host parameter seems to use only one host. Is it possible to specify multiple nodes? . . . . .	130
9.24	Is there any plan to implement a REST API into this project? . . . . .	130
9.25	An error occurred when trying to create a blacklist rule that parses a file with more than 1024 lines. . . . .	130
9.26	ElastAlert 2 doesn't have a listening port? . . . . .	130
9.27	I've set <i>ssl_show_warn</i> but it doesn't seem to work. . . . .	130
9.28	How to write a query filter for phrases containing spaces? . . . . .	131
9.29	Does ElastAlert 2 support Elasticsearch 8? . . . . .	131
9.30	Support multiple sns_topic_arn in Alert Amazon SNS(Simple Notification Service)? . . . . .	132
9.31	Support multiple telegram_room_id in Alert Telegram? . . . . .	132
9.32	Is it possible to set a timeout for connecting to and reading from es_host ? . . . . .	132
9.33	Is it possible to stop disabling rules for ElastAlert 2? . . . . .	132
9.34	Is there an introductory article about elastalert2? . . . . .	133

## 10 Indices and Tables

135

Contents:

## INTRODUCTION

ElastAlert 2 is a simple framework for alerting on anomalies, spikes, or other patterns of interest from data in [Elasticsearch](#) and [OpenSearch](#).

If you have data being written into Elasticsearch in near real time and want to be alerted when that data matches certain patterns, ElastAlert 2 is the tool for you.

### 1.1 Overview

We designed ElastAlert 2 to be *reliable*, highly *modular*, and easy to setup.

It works by combining Elasticsearch with two types of components, rules and alerts. The datasource, typically Elasticsearch, is periodically queried and the data is passed to the rule type, which determines when a match is found. When a match occurs, it is given to one or more alerts, which take action based on the match.

This is configured by a set of rules, each of which defines a query, a rule type, and a set of alerts.

Several rule types with common monitoring paradigms are included with ElastAlert 2:

- “Match where there are X events in Y time” (frequency type)
- “Match when the rate of events increases or decreases” (spike type)
- “Match when there are less than X events in Y time” (flatline type)
- “Match when a certain field matches a blacklist/whitelist” (blacklist and whitelist type)
- “Match on any event matching a given filter” (any type)
- “Match when a field has two different values within some time” (change type)

Currently, we have support built in for these alert types:

- Alerta
- Alertmanager
- AWS SES (Amazon Simple Email Service)
- AWS SNS (Amazon Simple Notification Service)
- Chatwork
- Command
- Datadog
- Debug
- Dingtalk

- Discord
- Email
- Exotel
- Gitter
- GoogleChat
- Graylog GELF
- HTTP POST
- HTTP POST 2
- Iris
- Jira
- Lark
- Line Notify
- Mattermost
- Microsoft Teams
- OpsGenie
- PagerDuty
- PagerTree
- Rocket.Chat
- Squadcast
- ServiceNow
- Slack
- Splunk On-Call (Formerly VictorOps)
- Stomp
- Telegram
- Tencent SMS
- TheHive
- Twilio
- WorkWechat
- Zabbix

Additional rule types and alerts can be easily imported or written. (See [Writing rule types](#) and [Writing alerts](#))

In addition to this basic usage, there are many other features that make alerts more useful:

- Alerts link to Kibana Discover searches
- Aggregate counts for arbitrary fields
- Combine alerts into periodic reports
- Separate alerts by using a unique key field
- Intercept and enhance match data

To get started, check out [Running ElastAlert 2 For The First Time](#).

## 1.2 Reliability

ElastAlert 2 has several features to make it more reliable in the event of restarts or Elasticsearch unavailability:

- ElastAlert 2 *saves its state to Elasticsearch* and, when started, will resume where previously stopped
- If Elasticsearch is unresponsive, ElastAlert 2 will wait until it recovers before continuing
- Alerts which throw errors may be automatically retried for a period of time

## 1.3 Modularity

ElastAlert 2 has three main components that may be imported as a module or customized:

### 1.3.1 Rule types

The rule type is responsible for processing the data returned from Elasticsearch. It is initialized with the rule configuration, passed data that is returned from querying Elasticsearch with the rule's filters, and outputs matches based on this data. See [Writing rule types](#) for more information.

### 1.3.2 Alerts

Alerts are responsible for taking action based on a match. A match is generally a dictionary containing values from a document in Elasticsearch, but may contain arbitrary data added by the rule type. See [Writing alerts](#) for more information.

### 1.3.3 Enhancements

Enhancements are a way of intercepting an alert and modifying or enhancing it in some way. They are passed the match dictionary before it is given to the alerter. See [Enhancements](#) for more information.

## GETTING STARTED

ElastAlert 2 can easily be run as *a Docker container* or directly on your machine as *a Python package*. If you are not interested in modifying the internals of ElastAlert 2, the Docker container is recommended for ease of use.

### 2.1 As a Docker container

If you're interested in a pre-built Docker image check out the elastalert2 container image on [Docker Hub](#) or [GitHub Container Registry](#). Both images are published for each release. Use GitHub Container Registry if you are running into Docker Hub usage limits.

Be aware that the `latest` tag of the image represents the latest commit into the master branch. If you prefer to upgrade more slowly you will need utilize a versioned tag, such as `2.17.0` instead, or `2` if you are comfortable with always using the latest released version of ElastAlert 2.

A properly configured `config.yaml` file must be mounted into the container during startup of the container. Use the [example file](#) as a template.

The following example assumes Elasticsearch container has already been started with Docker. This example also assumes both the Elasticsearch and ElastAlert2 containers are using the default Docker network: `es_default`

Create a rule directory and rules file in addition to `elastalert.yaml`, and then mount both into the ElastAlert 2 container:

```
elastalert.yaml
rules/
  a.yaml
```

elastalert.yaml

```
rules_folder: /opt/elastalert/rules

run_every:
  seconds: 10

buffer_time:
  minutes: 15

es_host: elasticsearch
es_port: 9200

writeback_index: elastalert_status
```

(continues on next page)

(continued from previous page)

```
alert_time_limit:
  days: 2
```

a.yaml

```
name: "a"
type: "frequency"
index: "mariadbblog-*"
is_enabled: true
num_events: 2
realert:
  minutes: 5
terms_size: 50
timeframe:
  minutes: 5
timestamp_field: "@timestamp"
timestamp_type: "iso"
use_strftime_index: false
alert_subject: "Test {} 123 aa"
alert_subject_args:
  - "message"
  - "@log_name"
alert_text: "Test {} 123 bb"
alert_text_args:
  - "message"
filter:
  - query:
      query_string:
        query: "@timestamp:*"
alert:
  - "slack"
slack_webhook_url: 'https://hooks.slack.com/services/xxxxxxx'
slack_channel_override: "#abc"
slack_emoji_override: ":kissing_cat:"
slack_msg_color: "warning"
slack_parse_override: "none"
slack_username_override: "elastalert"
```

Starting the container via Docker Hub (hub.docker.com)

```
docker run --net=es_default -d --name elastalert --restart=always \
-v $(pwd)/elastalert.yaml:/opt/elastalert/config.yaml \
-v $(pwd)/rules:/opt/elastalert/rules \
jertel/elastalert2 --verbose

docker logs -f elastalert
```

Starting the container via GitHub Container Registry (ghcr.io)

```
docker run --net=es_default -d --name elastalert --restart=always \
-v $(pwd)/elastalert.yaml:/opt/elastalert/config.yaml \
-v $(pwd)/rules:/opt/elastalert/rules \
ghcr.io/jertel/elastalert2/elastalert2 --verbose
```

(continues on next page)

(continued from previous page)

```
docker logs -f elastalert
```

For developers, the below command can be used to build the image locally:

```
docker build . -t elastalert2
```

## 2.2 As a Kubernetes deployment

The Docker container for ElastAlert 2 can be used directly as a Kubernetes deployment, but for convenience, a Helm chart is also available. See the instructions provided [on Github](#) for more information on how to install, configure, and run the chart.

## 2.3 As a Python package

This method is only recommended for advanced users, as providing support is very challenging due to the numerous differences between everyone's environment.

### 2.3.1 Requirements

- Elasticsearch 7.x or 8.x, or OpenSearch 1.x or 2.x
- ISO8601 or Unix timestamped data
- Python 3.12. Require OpenSSL 1.1.1 or newer.
- pip
- Packages on Ubuntu 21.x: build-essential python3-pip python3.12 python3.12-dev libffi-dev libssl-dev

If you want to install python 3.12 on CentOS, please install python 3.12 from the source code after installing 'Development Tools'.

### 2.3.2 Downloading and Configuring

You can either install the latest released version of ElastAlert 2 using pip:

```
$ pip install elastalert2
```

or you can clone the ElastAlert2 repository for the most recent changes:

```
$ git clone https://github.com/jertel/elastalert2.git
```

Install the module:

```
$ pip install "setuptools>=11.3"
$ python setup.py install
```

Next, open up `examples/config.yaml.example`. In it, you will find several configuration options. ElastAlert 2 may be run without changing any of these settings.

See *Global Configuration* for details on all the configuration options available.

Save the file as `config.yaml`

### 2.3.3 Manually Creating the ElastAlert 2 Indices

ElastAlert 2 saves information and metadata about its queries and its alerts back to Elasticsearch. This is useful for auditing, debugging, and it allows ElastAlert 2 to restart and resume exactly where it left off. This is not required for ElastAlert 2 to run, but highly recommended.

First, we need to create an index for ElastAlert 2 to write to by running `elastalert-create-index` and following the instructions. Note that this manual step is only needed by users that run ElastAlert 2 directly on the host, whereas container users will automatically see these indexes created on startup.:

```
$ elastalert-create-index
New index name (Default elastalert_status)
Name of existing index to copy (Default None)
New index elastalert_status created
Done!
```

For information about what data will go here, see *ElastAlert 2 Metadata Index*.

### 2.3.4 Starting ElastAlert 2 via Python CLI

There are two ways of invoking ElastAlert 2 without Docker. As a daemon, through Supervisor (<http://supervisord.org/>), or directly with Python as shown below:

```
$ python -m elastalert.elastalert --verbose --rule example_frequency.yaml # or use the
↳ entry point: elastalert --verbose --rule ...
```

The argument `--verbose` sets it to display INFO level messages, while `--rule example_frequency.yaml` specifies a single rule to run, otherwise ElastAlert 2 will attempt to load the other rules in the `examples/rules` folder.

## 2.4 Creating a Rule

Each rule defines a query to perform, parameters on what triggers a match, and a list of alerts to fire for each match. We are going to use `examples/rules/example_frequency.yaml` as a template:

```
# From examples/rules/example_frequency.yaml
es_host: elasticsearch.example.com
es_port: 14900
name: Example rule
type: frequency
index: logstash-*
num_events: 50
timeframe:
  hours: 4
filter:
- term:
```

(continues on next page)

(continued from previous page)

```

    some_field: "some_value"
  alert:
  - "email"
  email:
  - "elastalert@example.com"

```

`es_host` and `es_port` should point to the Elasticsearch cluster we want to query.

`name` is the unique name for this rule. ElastAlert 2 will not start if two rules share the same name.

`type`: Each rule has a different type which may take different parameters. The `frequency` type means “Alert when more than `num_events` occur within `timeframe`.” For information other types, see [Rule types](#).

`index`: The name of the index(es) to query. If you are using Logstash, by default the indexes will match “`logstash-*`”.

`num_events`: This parameter is specific to `frequency` type and is the threshold for when an alert is triggered.

`timeframe` is the time period in which `num_events` must occur.

`filter` is a list of Elasticsearch filters that are used to filter results. Here we have a single term filter for documents with `some_field` matching `some_value`. See [Writing Filters For Rules](#) for more information. If no filters are desired, it should be specified as an empty list: `filter: []`

`alert` is a list of alerts to run on each match. For more information on alert types, see [Alert Types](#). The email alert requires an SMTP server for sending mail. By default, it will attempt to use localhost. This can be changed with the `smtp_host` option.

`email` is a list of addresses to which alerts will be sent.

There are many other optional configuration options, see [Common configuration options](#).

All documents must have a timestamp field. ElastAlert 2 will try to use `@timestamp` by default, but this can be changed with the `timestamp_field` option. By default, ElastAlert 2 uses ISO8601 timestamps, though unix timestamps are supported by setting `timestamp_type`.

As is, this rule means “Send an email to `elastalert@example.com` when there are more than 50 documents with `some_field == some_value` within a 4 hour period.”

See [the testing section for more details](#) on how to test a specific rule file without sending alerts.

## 2.5 Operational Review

When ElastAlert 2 starts and output is configured to be sent to the console, it will resemble the following:

```

No handlers could be found for logger "Elasticsearch"
INFO:root:Queried rule Example rule from 1-15 14:22 PST to 1-15 15:07 PST: 5 hits
INFO:Elasticsearch:POST http://elasticsearch.example.com:14900/elastalert_status/
↳elastalert_status?op_type=create [status:201 request:0.025s]
INFO:root:Ran Example rule from 1-15 14:22 PST to 1-15 15:07 PST: 5 query hits (0
↳already seen), 0 matches, 0 alerts sent
INFO:root:Sleeping for 297 seconds

```

Let’s break down the response to see what’s happening.

Queried rule Example rule from 1-15 14:22 PST to 1-15 15:07 PST: 5 hits

ElastAlert 2 periodically queries the most recent `buffer_time` (default 45 minutes) for data matching the filters. Here we see that it matched 5 hits:

```
POST http://elasticsearch.example.com:14900/elastalert_status/elastalert_status?op_
↳type=create [status:201 request:0.025s]
```

This line showing that ElastAlert 2 uploaded a document to the elastalert\_status index with information about the query it just made:

```
Ran Example rule from 1-15 14:22 PST to 1-15 15:07 PST: 5 query hits (0 already seen), 0_
↳matches, 0 alerts sent
```

The line means ElastAlert 2 has finished processing the rule. For large time periods, sometimes multiple queries may be run, but their data will be processed together. `query hits` is the number of documents that are downloaded from Elasticsearch, `already seen` refers to documents that were already counted in a previous overlapping query and will be ignored, `matches` is the number of matches the rule type outputted, and `alerts sent` is the number of alerts actually sent. This may differ from `matches` because of options like `realert` and `aggregation` or because of an error.

Sleeping for 297 seconds

The default `run_every` is 5 minutes, meaning ElastAlert 2 will sleep until 5 minutes have elapsed from the last cycle before running queries for each rule again with time ranges shifted forward 5 minutes.

Say, over the next 297 seconds, 46 more matching documents were added to Elasticsearch:

```
INFO:root:Queried rule Example rule from 1-15 14:27 PST to 1-15 15:12 PST: 51 hits
...
INFO:root:Sent email to ['elastalert@example.com']
...
INFO:root:Ran Example rule from 1-15 14:27 PST to 1-15 15:12 PST: 51 query hits, 1_
↳matches, 1 alerts sent
```

The body of the email will contain something like:

```
Example rule

At least 50 events occurred between 1-15 11:12 PST and 1-15 15:12 PST

@timestamp: 2015-01-15T15:12:00-08:00
```

If an error occurred, such as an unreachable SMTP server, you may see:

```
ERROR:root:Error while running alert email: Error connecting to SMTP host: [Errno 61]_
↳Connection refused
```

Note that if you stop ElastAlert 2 and then run it again later, it will look up `elastalert_status` and begin querying at the end time of the last query. This is to prevent duplication or skipping of alerts if ElastAlert 2 is restarted.

By using the `--debug` flag instead of `--verbose`, the body of email will instead be logged and the email will not be sent. In addition, the queries will not be saved to `elastalert_status`.

## 2.6 Disabling a Rule

To stop a rule from executing, add or adjust the *is\_enabled* option inside the rule's YAML file to *false*. When ElastAlert 2 reloads the rules it will detect that the rule has been disabled and prevent it from executing. The rule reload interval defaults to 5 minutes but can be adjusted via the *run\_every* configuration option.

Optionally, once a rule has been disabled it is safe to remove the rule file, if there is no intention of re-activating the rule. However, be aware that removing a rule file without first disabling it will *\_not\_* disable the rule!

## COMMAND LINE FLAGS

ElastAlert 2 accepts several optional command line parameters:

`--config` will specify the configuration file to use. The default is `config.yaml`.

`--debug` will run ElastAlert 2 in debug mode. This will increase the logging verbosity, change all alerts to `DebugAlerter`, which prints alerts and suppresses their normal action, and skips writing search and alert metadata back to Elasticsearch. Not compatible with `--verbose`.

`--end <timestamp>` will force ElastAlert 2 to stop querying after the given time, instead of the default, querying to the present time. This really only makes sense when running standalone. The timestamp is formatted as `YYYY-MM-DDTHH:MM:SS (UTC)` or with timezone `YYYY-MM-DDTHH:MM:SS-XX:00 (UTC-XX)`.

`--es_debug` will enable logging for all queries made to Elasticsearch.

`--es_debug_trace <trace.log>` will enable logging curl commands for all queries made to Elasticsearch to the specified log file. `--es_debug_trace` is passed through to `elasticsearch.py` which logs `localhost:9200` instead of the actual `es_host:es_port`.

`--pin_rules` will stop ElastAlert 2 from loading, reloading or removing rules based on changes to their config files.

`--prometheus_port` exposes ElastAlert 2 `Prometheus metrics` on the specified port. Prometheus metrics disabled by default.

`--rule <rule.yaml>` will only run the given rule. The rule file may be a complete file path or a filename in `rules_folder` or its subdirectories.

`--silence <unit>=<number>` will silence the alerts for a given rule for a period of time. The rule must be specified using `--rule`. `<unit>` is one of days, weeks, hours, minutes or seconds. `<number>` is an integer. For example, `--rule noisy_rule.yaml --silence hours=4` will stop `noisy_rule` from generating any alerts for 4 hours.

`--silence_qk_value <value>` will silence the rule only for the given query key value. This parameter is intended to be used with the `--rule` parameter.

`--start <timestamp>` will force ElastAlert 2 to begin querying from the given time, instead of the default, querying from the present. The timestamp should be ISO8601, e.g. `YYYY-MM-DDTHH:MM:SS (UTC)` or with timezone `YYYY-MM-DDTHH:MM:SS-08:00 (PST)`. Note that if querying over a large date range, no alerts will be sent until that rule has finished querying over the entire time period. To force querying from the current time, use "NOW".

`--verbose` will increase the logging verbosity, which allows you to see information about the state of queries. Not compatible with `--debug`.

## GLOBAL CONFIGURATION

ElastAlert 2 has a global configuration file, `config.yaml`, which defines several aspects of its operation:

**buffer\_time:** ElastAlert 2 will continuously query against a window from the present to `buffer_time` ago. This way, logs can be back filled up to a certain extent and ElastAlert 2 will still process the events. This may be overridden by individual rules. This option is ignored for rules where `use_count_query` or `use_terms_query` is set to true. Note that back filled data may not always trigger count based alerts as if it was queried in real time.

**es\_host:** The host name of the Elasticsearch cluster where ElastAlert 2 records metadata about its searches. When ElastAlert 2 is started, it will query for information about the time that it was last run. This way, even if ElastAlert 2 is stopped and restarted, it will never miss data or look at the same events twice. It will also specify the default cluster for each rule to run on. The environment variable `ES_HOST` will override this field. For multiple host Elasticsearch clusters see `es_hosts` parameter.

**es\_port:** The port corresponding to `es_host`. The environment variable `ES_PORT` will override this field.

**es\_hosts** is the list of addresses of the nodes of the Elasticsearch cluster. This parameter can be used for high availability purposes, but the primary host must also be specified in the `es_host` parameter. The `es_hosts` parameter can be overridden within each rule. This value can be specified as `host:port` if overriding the default port. The environment variable `ES_HOSTS` will override this field, and can be specified as a comma-separated value to denote multiple hosts.

**use\_ssl:** Optional; whether or not to connect to `es_host` using TLS; set to `True` or `False`. The environment variable `ES_USE_SSL` will override this field.

**verify\_certs:** Optional; whether or not to verify TLS certificates; set to `True` or `False`. The default is `True`.

**ssl\_show\_warn:** Optional; suppress TLS and certificate related warnings; set to `True` or `False`. The default is `True`.

**client\_cert:** Optional; path to a PEM certificate to use as the client certificate.

**client\_key:** Optional; path to a private key file to use as the client key.

**ca\_certs:** Optional; path to a CA cert bundle to use to verify SSL connections

**es\_username:** Optional; basic-auth username for connecting to `es_host`. The environment variable `ES_USERNAME` will override this field.

**es\_password:** Optional; basic-auth password for connecting to `es_host`. The environment variable `ES_PASSWORD` will override this field.

**es\_bearer:** Optional; Bearer token for connecting to `es_host`. The environment variable `ES_BEARER` will override this field. This authentication option will override the password authentication option.

**es\_api\_key:** Optional; Base64 api-key token for connecting to `es_host`. The environment variable `ES_API_KEY` will override this field. This authentication option will override both the bearer and the password authentication options.

**es\_url\_prefix:** Optional; URL prefix for the Elasticsearch endpoint. The environment variable `ES_URL_PREFIX` will override this field.

**es\_send\_get\_body\_as:** Optional; Method for querying Elasticsearch - GET, POST or source. The default is GET

`es_conn_timeout`: Optional; sets timeout for connecting to and reading from `es_host`; defaults to 20.

`rules_loader`: Optional; sets the loader class to be used by ElastAlert 2 to retrieve rules and hashes. Defaults to `FileRulesLoader` if not set.

`rules_folder`: The name of the folder or a list of folders which contains rule configuration files. ElastAlert 2 will load all files in this folder, and all subdirectories, that end in `.yaml`. If the contents of this folder change, ElastAlert 2 will load, reload or remove rules based on their respective config files. (only required when using `FileRulesLoader`).

`scan_subdirectories`: Optional; Sets whether or not ElastAlert 2 should recursively descend the rules directory - `true` or `false`. The default is `true`

`run_every`: How often ElastAlert 2 should query Elasticsearch. ElastAlert 2 will remember the last time it ran the query for a given rule, and periodically query from that time until the present. The format of this field is a nested unit of time, such as `minutes: 5`. This is how time is defined in every ElastAlert 2 configuration.

`misfire_grace_time`: If the rule scheduler is running behind, due to large numbers of rules or long-running rules, this grace time settings allows a rule to still be executed, provided its next scheduled run time is no more than this grace period, in seconds, overdue. The default is 5 seconds.

`writeback_index`: The index on `es_host` to use.

`max_query_size`: The maximum number of documents that will be downloaded from Elasticsearch in a single query. The default is 10,000, and if you expect to get near this number, consider using `use_count_query` for the rule. If this limit is reached, ElastAlert 2 will `scroll` using the size of `max_query_size` through the set amount of pages, when `max_scrolling_count` is set or until processing all results.

`max_scrolling_count`: The maximum amount of pages to scroll through. The default is 990, to avoid a stack overflow error due to Python's stack limit of 1000. For example, if this value is set to 5 and the `max_query_size` is set to 10000 then 50000 documents will be downloaded at most.

`max_threads`: The maximum number of concurrent threads available to process scheduled rules. Large numbers of long-running rules may require this value be increased, though this could overload the Elasticsearch cluster if too many complex queries are running concurrently. Default is 10.

`scroll_keepalive`: The maximum time (formatted in `Time Units`) the scrolling context should be kept alive. Avoid using high values as it abuses resources in Elasticsearch, but be mindful to allow sufficient time to finish processing all the results.

`max_aggregation`: The maximum number of alerts to aggregate together. If a rule has `aggregation` set, all alerts occurring within a timeframe will be sent together. The default is 10,000.

`old_query_limit`: The maximum time between queries for ElastAlert 2 to start at the most recently run query. When ElastAlert 2 starts, for each rule, it will search `elastalert_metadata` for the most recently run query and start from that time, unless it is older than `old_query_limit`, in which case it will start from the present time. The default is one week.

`disable_rules_on_error`: If true, ElastAlert 2 will disable rules which throw uncaught (not `EAException`) exceptions. It will upload a traceback message to `elastalert_metadata` and if `notify_email` is set, send an email notification. The rule will no longer be run until either ElastAlert 2 restarts or the rule file has been modified. This defaults to `True`.

`show_disabled_rules`: If true, ElastAlert 2 show the disable rules' list when finishes the execution. This defaults to `True`.

`notify_email`: An email address, or list of email addresses, to which notification emails will be sent. Currently, only an uncaught exception will send a notification email. The from address, SMTP host, and reply-to header can be set using `from_addr`, `smtp_host`, and `email_reply_to` options, respectively. By default, no emails will be sent.

single address example:

```
notify_email: "one@domain"
```

or

multiple address example:

```
notify_email:
  - "one@domain"
  - "two@domain"
```

**from\_addr:** The address to use as the from header in email notifications. This value will be used for email alerts as well, unless overwritten in the rule config. The default value is “ElastAlert”.

**smtp\_host:** The SMTP host used to send email notifications. This value will be used for email alerts as well, unless overwritten in the rule config. The default is “localhost”.

**email\_reply\_to:** This sets the Reply-To header in emails. The default is the recipient address.

**aws\_region:** This makes ElastAlert 2 to sign HTTP requests when using Amazon OpenSearch Service. It'll use instance role keys to sign the requests. The environment variable `AWS_DEFAULT_REGION` will override this field.

**profile:** AWS profile to use when signing requests to Amazon OpenSearch Service, if you don't want to use the instance role keys. The environment variable `AWS_DEFAULT_PROFILE` will override this field.

**replace\_dots\_in\_field\_names:** If True, ElastAlert 2 replaces any dots in field names with an underscore before writing documents to Elasticsearch. The default value is False. Elasticsearch 2.0 - 2.3 does not support dots in field names.

**string\_multi\_field\_name:** If set, the suffix to use for the subfield for string multi-fields in Elasticsearch. The default value is `.keyword`.

**add\_metadata\_alert:** If set, alerts will include metadata described in rules (category, description, owner and priority); set to True or False. The default is False.

**skip\_invalid:** If True, skip invalid files instead of exiting.

**jinja\_root\_name:** When using a Jinja template, specify the name of the root field name in the template. The default is `_data`.

**jinja\_template\_path:** When using a Jinja template, specify relative (based on current working directory) filesystem path to template, this overrides the default behaviour of using `alert_text` as the template.

**custom\_pretty\_ts\_format:** This option provides a way to define custom format of timestamps printed in log messages and in alert messages. If this option is not set, default timestamp format (`'%Y-%m-%d %H:%M %Z'`) will be used. (Optional, string, default None)

Example usage and resulting formatted timestamps:

```
(not set; default)      -> '2021-08-16 21:38 JST'
custom_pretty_ts_format: '%Y-%m-%d %H:%M %Z' -> '2021-08-16 21:38 +0900'
custom_pretty_ts_format: '%Y-%m-%d %H:%M'   -> '2021-08-16 21:38'
```

Examples of several types of rule configuration can be found in the `examples/rules` folder.

---

**Note:** All “time” formats are of the form `unit: X` where unit is one of weeks, days, hours, minutes or seconds. Such as `minutes: 15` or `hours: 1`.

## 5.2 Common Configuration Options

Every file that ends in `.yaml` in the `rules_folder` will be run by default. The following configuration settings are common to all types of rules.

**Note:** While the following are marked as *required*, if they are already defined in the global configuration then those settings will be utilized. If desired, each rule can override the global settings.

### 5.2.1 Required Settings

#### `es_host`

`es_host`: The hostname of the Elasticsearch cluster the rule will use to query. (Required, string, no default) The environment variable `ES_HOST` will override this field. For multiple host Elasticsearch clusters see `es_hosts` parameter.

#### `es_port`

`es_port`: The port of the Elasticsearch cluster. (Required, number, no default) The environment variable `ES_PORT` will override this field.

#### `index`

`index`: The name of the index that will be searched. Wildcards can be used here, such as: `index: my-index-*` which will match `my-index-2014-10-05`. You can also use a format string containing `%Y` for year, `%m` for month, and `%d` for day. To use this, you must also set `use_strftime_index` to true. (Required, string, no default)

For example, Separate multiple indices with commas.:

```
index: topbeat-*,packetbeat-*
```

**name**

**name:** The name of the rule. This must be unique across all rules. The name will be used in alerts and used as a key when writing and reading search metadata back from Elasticsearch. (Required, string, no default)

**type**

**type:** The RuleType to use. This may either be one of the built in rule types, see [Rule Types](#) section below for more information, or loaded from a module. For loading from a module, the type should be specified as `module.file.RuleName`. (Required, string, no default)

**alert**

**alert:** The Alerter type to use. This may be one or more of the built in alerts, see [Alert Types](#) section below for more information, or loaded from a module. For loading from a module, the alert should be specified as `module.file.AlertName`. (Required, string or list, no default)

## 5.2.2 Optional Settings

**es\_hosts**

**es\_hosts:** The list of nodes of the Elasticsearch cluster that the rule will use for the request. (Optional, list, default none). Values can be specified as `host:port` if overriding the default port. The environment variable `ES_HOSTS` will override this field, and can be specified as a comma-separated value. Note that the `es_host` parameter must still be specified in order to identify a primary Elasticsearch host.

**import**

**import:** If specified includes all the settings from this yaml file. This allows common config options to be shared. Note that imported files that aren't complete rules should not have a `.yaml` or `.yml` suffix so that ElastAlert 2 doesn't treat them as rules. Filters in imported files are merged (ANDed) with any filters in the rule. You can have one import per rule (value is string) or several imports per rule (value is a list of strings). The imported file can import another file or multiple files, recursively. The filename can be an absolute path or relative to the rules directory. (Optional, string or array of strings, no default)

**use\_ssl**

**use\_ssl:** Whether or not to connect to `es_host` using TLS. (Optional, boolean, default False) The environment variable `ES_USE_SSL` will override this field.

### **ssl\_show\_warn**

`ssl_show_warn`: Whether or not to show SSL/TLS warnings when `verify_certs` is disabled. (Optional, boolean, default True)

### **verify\_certs**

`verify_certs`: Whether or not to verify TLS certificates. (Optional, boolean, default True)

### **client\_cert**

`client_cert`: Path to a PEM certificate to use as the client certificate (Optional, string, no default)

### **client\_key**

`client_key`: Path to a private key file to use as the client key (Optional, string, no default)

### **ca\_certs**

`ca_certs`: Path to a CA cert bundle to use to verify SSL connections (Optional, string, no default)

### **disable\_rules\_on\_error**

`disable_rules_on_error`: If true, ElastAlert 2 will disable rules which throw uncaught (not `EAlertException`) exceptions. It will upload a traceback message to `elastalert_metadata` and if `notify_email` is set, send an email notification. The rule will no longer be run until either ElastAlert 2 restarts or the rule file has been modified. This defaults to True.

### **es\_conn\_timeout**

`es_conn_timeout`: Optional; sets timeout for connecting to and reading from `es_host`; defaults to 20.

### **es\_username**

`es_username`: basic-auth username for connecting to `es_host`. (Optional, string, no default) The environment variable `ES_USERNAME` will override this field.

### **es\_password**

`es_password`: basic-auth password for connecting to `es_host`. (Optional, string, no default) The environment variable `ES_PASSWORD` will override this field.

**es\_bearer**

**es\_bearer:** bearer-token authorization for connecting to **es\_host**. (Optional, string, no default) The environment variable **ES\_BEARER** will override this field. This authentication option will override the password authentication option.

**es\_api\_key**

**es\_api\_key:** api-key-token authorization for connecting to **es\_host**. (Optional, base64 string, no default) The environment variable **ES\_API\_KEY** will override this field. This authentication option will override both the bearer and the password authentication options.

**es\_url\_prefix**

**es\_url\_prefix:** URL prefix for the Elasticsearch endpoint. (Optional, string, no default)

**statsd\_instance\_tag**

**statsd\_instance\_tag:** prefix for statsd metrics. (Optional, string, no default)

**statsd\_host**

**statsd\_host:** statsd host. (Optional, string, no default)

**es\_send\_get\_body\_as**

**es\_send\_get\_body\_as:** Method for querying Elasticsearch. (Optional, string, default “GET”)

**use\_strftime\_index**

**use\_strftime\_index:** If this is true, ElastAlert 2 will format the index using `datetime.strftime` for each query. See <https://docs.python.org/2/library/datetime.html#strftime-strptime-behavior> for more details. If a query spans multiple days, the formatted indexes will be concatenated with commas. This is useful as narrowing the number of indexes searched, compared to using a wildcard, may be significantly faster. For example, if **index** is `logstash-%Y.%m.%d`, the query url will be similar to `elasticsearch.example.com/logstash-2015.02.03/...` or `elasticsearch.example.com/logstash-2015.02.03,logstash-2015.02.04/...`

**search\_extra\_index**

**search\_extra\_index:** If this is true, ElastAlert 2 will add an extra index on the early side onto each search. For example, if it's querying completely within 2018-06-28, it will actually use 2018-06-27,2018-06-28. This can be useful if your **timestamp\_field** is not what's being used to generate the index names. If that's the case, sometimes a query would not have been using the right index.

## aggregation

**aggregation:** This option allows you to aggregate multiple matches together into one alert. Every time a match is found, ElastAlert 2 will wait for the aggregation period, and send all of the matches that have occurred in that time for a particular rule together.

For example:

```
aggregation:
  hours: 2
```

means that if one match occurred at 12:00, another at 1:00, and a third at 2:30, one alert would be sent at 2:00, containing the first two matches, and another at 4:30, containing the third match plus any additional matches occurring before 4:30. This can be very useful if you expect a large number of matches and only want a periodic report. (Optional, time, default none)

If you wish to aggregate all your alerts and send them on a recurring interval, you can do that using the `schedule` field.

For example, if you wish to receive alerts every Monday and Friday:

```
aggregation:
  schedule: '2 4 * * mon,fri'
```

This uses Cron syntax, which you can read more about [here](#). Make sure to *only* include either a schedule field or standard datetime fields (such as `hours`, `minutes`, `days`), not both.

By default, all events that occur during an aggregation window are grouped together. However, if your rule has the `aggregation_key` field set, then each event sharing a common key value will be grouped together. A separate aggregation window will be made for each newly encountered key value.

For example, if you wish to receive alerts that are grouped by the user who triggered the event, you can set:

```
aggregation_key: 'my_data.username'
```

Then, assuming an aggregation window of 10 minutes, if you receive the following data points:

```
{'my_data': {'username': 'alice', 'event_type': 'login'}, '@timestamp': '2016-09-20T00:00:00'}
{'my_data': {'username': 'bob', 'event_type': 'something'}, '@timestamp': '2016-09-20T00:05:00'}
{'my_data': {'username': 'alice', 'event_type': 'something else'}, '@timestamp': '2016-09-20T00:06:00'}
```

This should result in 2 alerts: One containing alice's two events, sent at `2016-09-20T00:10:00` and one containing bob's one event sent at `2016-09-20T00:16:00`

For aggregations, there can sometimes be a large number of documents present in the viewing medium (email, Jira ticket, etc...). If you set the `summary_table_fields` field, ElastAlert 2 will provide a summary of the specified fields from all the results.

The formatting style of the summary table can be switched between `ascii` (default), `markdown`, or `html` with parameter `summary_table_type`.

The maximum number of rows in the summary table can be limited with the parameter `summary_table_max_rows`.

For example, if you wish to summarize the usernames and event\_types that appear in the documents so that you can see the most relevant fields at a quick glance, you can set:

```
summary_table_fields:
  - my_data.username
  - my_data.event_type
```

Then, for the same sample data shown above listing alice and bob's events, ElastAlert 2 will provide the following summary table in the alert medium:

```
+-----+-----+
| my_data.username | my_data.event_type |
+-----+-----+
|      alice      |      login         |
|       bob       |     something      |
|      alice      | something else     |
+-----+-----+
```

**Note:** By default, aggregation time is relative to the current system time, not the time of the match. This means that running ElastAlert 2 over past events will result in different alerts than if ElastAlert 2 had been running while those events occurred. This behavior can be changed by setting `aggregate_by_match_time`.

### limit\_execution

`limit_execution`: This option allows you to activate the rule during a limited period of time. This uses the cron format.

For example, if you wish to activate the rule from monday to friday, between 10am to 6pm:

```
limit_execution: "* 10-18 * * 1-5"
```

### aggregate\_by\_match\_time

Setting this to true will cause aggregations to be created relative to the timestamp of the first event, rather than the current time. This is useful for querying over historic data or if using a very large `buffer_time` and you want multiple aggregations to occur from a single query.

### realert

`realert`: This option allows you to ignore repeating alerts for a period of time. If the rule uses a `query_key`, this option will be applied on a per key basis. All matches for a given rule, or for matches with the same `query_key`, will be ignored for the given time. All matches with a missing `query_key` will be grouped together using a value of `_missing`. This is applied to the time the alert is sent, not to the time of the event. It defaults to one minute, which means that if ElastAlert 2 is run over a large time period which triggers many matches, only the first alert will be sent by default. If you want every alert, set `realert` to 0 minutes. (Optional, time, default 1 minute)

### realert\_key

**realert\_key:** This option allows you to customize the key for **realert**. The default is the rule name, but if you have multiple rules that you would like to use the same key for you can set the **realert\_key** to be the same in those rules. (Optional, string, default is the rule name)

### exponential\_realert

**exponential\_realert:** This option causes the value of **realert** to exponentially increase while alerts continue to fire. If set, the value of **exponential\_realert** is the maximum **realert** will increase to. If the time between alerts is less than twice **realert**, **realert** will double. For example, if **realert: minutes: 10** and **exponential\_realert: hours: 1**, an alerts fires at 1:00 and another at 1:15, the next alert will not be until at least 1:35. If another alert fires between 1:35 and 2:15, **realert** will increase to the 1 hour maximum. If more than 2 hours elapse before the next alert, **realert** will go back down. Note that alerts that are ignored (e.g. one that occurred at 1:05) would not change **realert**. (Optional, time, no default)

### buffer\_time

**buffer\_time:** This options allows the rule to override the **buffer\_time** global setting defined in **config.yaml**. This value is ignored if **use\_count\_query** or **use\_terms\_query** is true. (Optional, time)

### query\_delay

**query\_delay:** This option will cause ElastAlert 2 to subtract a time delta from every query, causing the rule to run with a delay. This is useful if the data is Elasticsearch doesn't get indexed immediately. (Optional, time)

For example:

```
query_delay:
  hours: 2
```

### owner

**owner:** This value will be used to identify the stakeholder of the alert. Optionally, this field can be included in any alert type. (Optional, string)

### priority

**priority:** This value will be used to identify the relative priority of the alert. Optionally, this field can be included in any alert type (e.g. for use in email subject/body text). (Optional, int, default 2)

### category

**category:** This value will be used to identify the category of the alert. Optionally, this field can be included in any alert type (e.g. for use in email subject/body text). (Optional, string, default empty string)

### max\_query\_size

**max\_query\_size:** The maximum number of documents that will be downloaded from Elasticsearch in a single query. If you expect a large number of results, consider using `use_count_query` for the rule. If this limit is reached, a warning will be logged but ElastAlert 2 will continue without downloading more results. This setting will override a global `max_query_size`. (Optional, int, default value of global `max_query_size`)

### filter

**filter:** A list of Elasticsearch query DSL filters that is used to query Elasticsearch. ElastAlert 2 will query Elasticsearch using the format `{'filter': {'bool': {'must': [config.filter]}}}` with an additional timestamp range filter. All of the results of querying with these filters are passed to the `RuleType` for analysis. For more information writing filters, see [Writing Filters](#). (Required, Elasticsearch query DSL, no default)

### include

**include:** A list of terms that should be included in query results and passed to rule types and alerts. When set, only those fields, along with `'@timestamp'`, `query_key`, `compare_key`, and `top_count_keys` are included, if present. (Optional, list of strings, default all fields)

### include\_fields

**include\_fields:** A list of fields that should be included in query results and passed to rule types and alerts. If `_source_enabled` is `False`, only these fields and those from `include` are included. When `_source_enabled` is `True`, these are in addition to source. This is used for runtime fields, script fields, etc. This only works with Elasticsearch version 7.11 and newer. (Optional, list of strings, no default)

### top\_count\_keys

**top\_count\_keys:** A list of fields. ElastAlert 2 will perform a terms query for the top X most common values for each of the fields, where X is 5 by default, or `top_count_number` if it exists. For example, if `num_events` is 100, and `top_count_keys` is `- "username"`, the alert will say how many of the 100 events have each username, for the top 5 usernames. When this is computed, the time range used is from `timeframe` before the most recent event to 10 minutes past the most recent event. Because ElastAlert 2 uses an aggregation query to compute this, it will attempt to use the field name plus `“.keyword”` to count unanalyzed terms. To turn this off, set `raw_count_keys` to `false`.

### **top\_count\_number**

**top\_count\_number:** The number of terms to list if **top\_count\_keys** is set. (Optional, integer, default 5)

### **raw\_count\_keys**

**raw\_count\_keys:** If true, all fields in **top\_count\_keys** will have **.keyword** appended to them. This used to be **“.raw”** in older Elasticsearch versions, but the setting name **raw\_count\_keys** was left as-is to avoid breaking existing installations. (Optional, boolean, default true)

### **description**

**description:** text describing the purpose of rule. (Optional, string, default empty string) Can be referenced in custom alerters to provide context as to why a rule might trigger.

### **kibana\_url**

**kibana\_url:** The base url of the Kibana application. If not specified, a URL will be constructed using **es\_host** and **es\_port**.

This value will be used if **generate\_kibana\_discover\_url** is true and **kibana\_discover\_app\_url** is a relative path

(Optional, string, default `http://<es_host>:<es_port>/_plugin/kibana/`)

### **kibana\_username**

**kibana\_username:** The username used to make basic authenticated API requests against Kibana. This value is only used if **shorten\_kibana\_discover\_url** is true.

(Optional, string, no default)

### **kibana\_password**

**kibana\_password:** The password used to make basic authenticated API requests against Kibana. This value is only used if **shorten\_kibana\_discover\_url** is true.

(Optional, string, no default)

### **kibana\_verify\_certs**

**kibana\_verify\_certs:** Whether or not to verify TLS certificates when querying Kibana. (Optional, boolean, default True)

### generate\_kibana\_discover\_url

`generate_kibana_discover_url`: Enables the generation of the `kibana_discover_url` variable for the Kibana Discover application. This setting requires the following settings are also configured:

- `kibana_discover_app_url`
- `kibana_discover_version`
- `kibana_discover_index_pattern_id`

`generate_kibana_discover_url`: `true`

Example `kibana_discover_app_url` only usage:

```
generate_kibana_discover_url: true
kibana_discover_app_url: "http://localhost:5601/app/discover#/"
kibana_discover_index_pattern_id: "4babf380-c3b1-11eb-b616-1b59c2feec54"
kibana_discover_version: "7.15"
alert_text: '{} '
alert_text_args: [ kibana_discover_url ]
alert_text_type: alert_text_only
```

Example `kibana_url` + `kibana_discover_app_url` usage:

```
generate_kibana_discover_url: true
kibana_url: "http://localhost:5601/"
kibana_discover_app_url: "app/discover#/"
kibana_discover_index_pattern_id: "4babf380-c3b1-11eb-b616-1b59c2feec54"
kibana_discover_version: "7.15"
alert_text: '{} '
alert_text_args: [ kibana_discover_url ]
alert_text_type: alert_text_only
```

### shorten\_kibana\_discover\_url

`shorten_kibana_discover_url`: Enables the shortening of the generated Kibana Discover urls. In order to use the Kibana Shorten URL REST API, the `kibana_discover_app_url` must be provided as a relative url (e.g. `app/discover?#/`).

ElastAlert may need to authenticate with Kibana to invoke the Kibana Shorten URL REST API. The supported authentication methods are:

- Basic authentication by specifying `kibana_username` and `kibana_password`
- AWS authentication (if configured already for Elasticsearch)

(Optional, bool, false)

### **kibana\_discover\_app\_url**

**kibana\_discover\_app\_url:** The url of the Kibana Discover application used to generate the **kibana\_discover\_url** variable. This value can use *\$VAR* and *\$/VAR/* references to expand environment variables. This value should be relative to the base kibana url defined by **kibana\_url** and will vary depending on your installation.

**kibana\_discover\_app\_url:** `app/discover#/`

(Optional, string, no default)

### **kibana\_discover\_security\_tenant**

**kibana\_discover\_security\_tenant:** The Kibana security tenant to include in the generated **kibana\_discover\_url** variable.

(Optional, string, no default)

### **kibana\_discover\_version**

**kibana\_discover\_version:** Specifies the version of the Kibana Discover application.

The currently supported versions of Kibana Discover are:

- *7.0, 7.1, 7.2, 7.3, 7.4, 7.5, 7.6, 7.7, 7.8, 7.9, 7.10, 7.11, 7.12, 7.13, 7.14, 7.15, 7.16, 7.17*
- *8.0, 8.1, 8.2, 8.3, 8.4, 8.5, 8.6, 8.7, 8.8, 8.9, 8.10, 8.11, 8.12, 8.13*

**kibana\_discover\_version:** `'7.15'`

### **kibana\_discover\_index\_pattern\_id**

**kibana\_discover\_index\_pattern\_id:** The id of the index pattern to link to in the Kibana Discover application. These ids are usually generated and can be found in url of the index pattern management page, or by exporting its saved object.

In this documentation all references of “index pattern” refer to the similarly named concept in Kibana 8 called “data view”.

Example export of an index pattern’s saved object:

```
[
  {
    "_id": "4e97d188-8a45-4418-8a37-07ed69b4d34c",
    "_type": "index-pattern",
    "_source": { ... }
  }
]
```

You can modify an index pattern’s id by exporting the saved object, modifying the `_id` field, and re-importing.

**kibana\_discover\_index\_pattern\_id:** `4e97d188-8a45-4418-8a37-07ed69b4d34c`

### kibana\_discover\_columns

kibana\_discover\_columns: The columns to display in the generated Kibana Discover application link. Defaults to the `_source` column.

```
kibana_discover_columns: [ timestamp, message ]
```

### kibana\_discover\_from\_timedelta

kibana\_discover\_from\_timedelta: The offset to the *from* time of the Kibana Discover link's time range. The *from* time is calculated by subtracting this timedelta from the event time. Defaults to 10 minutes.

```
kibana_discover_from_timedelta: minutes: 2
```

### kibana\_discover\_to\_timedelta

kibana\_discover\_to\_timedelta: The offset to the *to* time of the Kibana Discover link's time range. The *to* time is calculated by adding this timedelta to the event time. Defaults to 10 minutes.

```
kibana_discover_to_timedelta: minutes: 2
```

### opensearch\_url

opensearch\_url: The base url of the opensearch application. If not specified, a URL will be constructed using `es_host` and `es_port`.

This value will be used if `generate_opensearch_discover_url` is true and `opensearch_discover_app_url` is a relative path

(Optional, string, default `http://<opensearch_host>:<opensearch_port>/_plugin/_dashboards/`)

### generate\_opensearch\_discover\_url

generate\_opensearch\_discover\_url: Enables the generation of the `opensearch_discover_url` variable for the Opensearch Discover application. This setting requires the following settings are also configured:

- `opensearch_discover_app_url`
- `opensearch_discover_version`
- `opensearch_discover_index_pattern_id`

```
generate_opensearch_discover_url: true
```

Example `opensearch_discover_app_url` only usage for opensearch:

```
generate_opensearch_discover_url: true
opensearch_discover_app_url: "http://localhost:5601/app/data-explorer/discover?security_tenant=Admin#"
opensearch_discover_index_pattern_id: "4babf380-c3b1-11eb-b616-1b59c2feec54"
opensearch_discover_version: "2.11"
alert_text: '{}'
alert_text_args: [ opensearch_discover_url ]
alert_text_type: alert_text_only
```

Example `opensearch_url` + `opensearch_discover_app_url` usage for opensearch:

```
generate_opensearch_discover_url: true
opensearch_url: "http://localhost:5601/"
opensearch_discover_app_url: "app/data-explorer/discover?security_tenant=Admin#"
opensearch_discover_index_pattern_id: "4babf380-c3b1-11eb-b616-1b59c2feec54"
opensearch_discover_version: "2.11"
alert_text: '{} '
alert_text_args: [ opensearch_discover_url ]
alert_text_type: alert_text_only
```

### opensearch\_discover\_app\_url

`opensearch_discover_app_url`: The url of the opensearch Discover application used to generate the `opensearch_discover_url` variable. This value can use `$VAR` and `#{VAR}` references to expand environment variables. This value should be relative to the base opensearch url defined by `opensearch_url` and will vary depending on your installation.

`opensearch_discover_app_url`: `app/discover#/`

(Optional, string, no default)

### opensearch\_discover\_version

`opensearch_discover_version`: Specifies the version of the opensearch Discover application.

The currently supported versions of opensearch Discover are:

- *2.11*

`opensearch_discover_version`: `'2.11'`

### opensearch\_discover\_index\_pattern\_id

`opensearch_discover_index_pattern_id`: The id of the index pattern to link to in the opensearch Discover application. These ids are usually generated and can be found in url of the index pattern management page, or by exporting its saved object.

Example export of an index pattern's saved object:

```
[
  {
    "_id": "4e97d188-8a45-4418-8a37-07ed69b4d34c",
    "_type": "index-pattern",
    "_source": { ... }
  }
]
```

You can modify an index pattern's id by exporting the saved object, modifying the `_id` field, and re-importing.

`opensearch_discover_index_pattern_id`: `4e97d188-8a45-4418-8a37-07ed69b4d34c`

### **opensearch\_discover\_columns**

`opensearch_discover_columns`: The columns to display in the generated opensearch Discover application link. Defaults to the `_source` column.

```
opensearch_discover_columns: [ timestamp, message ]
```

### **opensearch\_discover\_from\_timedelta**

`opensearch_discover_from_timedelta`: The offset to the *from* time of the opensearch Discover link's time range. The *from* time is calculated by subtracting this timedelta from the event time. Defaults to 10 minutes.

```
opensearch_discover_from_timedelta: minutes: 2
```

### **opensearch\_discover\_to\_timedelta**

`opensearch_discover_to_timedelta`: The offset to the *to* time of the opensearch Discover link's time range. The *to* time is calculated by adding this timedelta to the event time. Defaults to 10 minutes.

```
opensearch_discover_to_timedelta: minutes: 2
```

### **use\_local\_time**

`use_local_time`: Whether to convert timestamps to the local time zone in alerts. If false, timestamps will be converted to UTC, which is what ElastAlert 2 uses internally. (Optional, boolean, default true)

### **match\_enhancements**

`match_enhancements`: A list of enhancement modules to use with this rule. An enhancement module is a subclass of `enhancements.BaseEnhancement` that will be given the match dictionary and can modify it before it is passed to the alerter. The enhancements will be run after silence and realert is calculated and in the case of aggregated alerts, right before the alert is sent. This can be changed by setting `run_enhancements_first`. The enhancements should be specified as `module.file.EnhancementName`. See [Enhancements](#) for more information. (Optional, list of strings, no default)

### **run\_enhancements\_first**

`run_enhancements_first`: If set to true, enhancements will be run as soon as a match is found. This means that they can be changed or dropped before affecting realert or being added to an aggregation. Silence stashes will still be created before the enhancement runs, meaning even if a `DropMatchException` is raised, the rule will still be silenced. (Optional, boolean, default false)

### **query\_key**

**query\_key**: Having a query key means that realert time will be counted separately for each unique value of **query\_key**. For rule types which count documents, such as spike, frequency and flatline, it also means that these counts will be independent for each unique value of **query\_key**. For example, if **query\_key** is set to **username** and **realert** is set, and an alert triggers on a document with `{ 'username': 'bob' }`, additional alerts for `{ 'username': 'bob' }` will be ignored while other usernames will trigger alerts. Documents which are missing the **query\_key** will be grouped together. A list of fields may also be used, which will create a compound query key. This compound key is treated as if it were a single field whose value is the component values, or “None”, joined by commas. A new field with the key “field1,field2,etc” will be created in each document and may conflict with existing fields of the same name.

### **aggregation\_key**

**aggregation\_key**: Having an aggregation key in conjunction with an aggregation will make it so that each new value encountered for the **aggregation\_key** field will result in a new, separate aggregation window.

### **summary\_table\_fields**

**summary\_table\_fields**: Specifying the **summary\_table\_fields** in conjunction with an aggregation will make it so that each aggregated alert will contain a table summarizing the values for the specified fields in all the matches that were aggregated together.

### **summary\_table\_type**

**summary\_table\_type**: One of: `ascii` or `markdown` or `html`. Select the table type to use for the aggregation summary. Defaults to `ascii` for the classical text based table.

### **summary\_table\_max\_rows**

**summary\_table\_max\_rows**: Limit the maximum number of rows that will be shown in the summary table.

### **summary\_prefix**

**summary\_prefix**: Specify a prefix string, which will be added in front of the aggregation summary table. This string is currently not subject to any formatting.

### **summary\_suffix**

**summary\_suffix**: Specify a suffix string, which will be added after the aggregation summary table. This string is currently not subject to any formatting.

## timestamp\_type

**timestamp\_type:** One of `iso`, `unix`, `unix_ms`, `custom`. This option will set the type of `@timestamp` (or `timestamp_field`) used to query Elasticsearch. `iso` will use ISO8601 timestamps, which will work with most Elasticsearch date type field. `unix` will query using an integer unix (seconds since 1/1/1970) timestamp. `unix_ms` will use milliseconds unix timestamp. `custom` allows you to define your own `timestamp_format`. The default is `iso`. (Optional, string enum, default `iso`).

## timestamp\_format

**timestamp\_format:** In case Elasticsearch used custom date format for date type field, this option provides a way to define custom timestamp format to match the type used for Elasticsearch date type field. This option is only valid if `timestamp_type` set to `custom`. (Optional, string, default `'%Y-%m-%dT%H:%M:%SZ'`).

## timestamp\_format\_expr

**timestamp\_format\_expr:** In case Elasticsearch used custom date format for date type field, this option provides a way to adapt the value obtained converting a datetime through `timestamp_format`, when the format cannot match perfectly what defined in Elasticsearch. When set, this option is evaluated as a Python expression along with a *globals* dictionary containing the original datetime instance named `dt` and the timestamp to be refined, named `ts`. The returned value becomes the timestamp obtained from the datetime. For example, when the date type field in Elasticsearch uses milliseconds (`yyyy-MM-dd'T'HH:mm:ss.SSS'Z'`) and `timestamp_format` option is `'%Y-%m-%dT%H:%M:%S.%fZ'`, Elasticsearch would fail to parse query terms as they contain microsecond values - that is it gets 6 digits instead of 3 - since the `%f` placeholder stands for microseconds for Python *strftime* method calls. Setting `timestamp_format_expr: 'ts[:23] + ts[26:]'` will truncate the value to milliseconds granting Elasticsearch compatibility. This option is only valid if `timestamp_type` set to `custom`. (Optional, string, no default).

## timestamp\_to\_datetime\_format\_expr

**timestamp\_to\_datetime\_format\_expr:** In the same spirit as `timestamp_format_expr`, in case Elasticsearch used custom date format for date type field, this option provides a way to adapt the value (as a string) returned by an Elasticsearch query before converting it into a datetime used by elastalert. The changes are applied before converting the timestamp string to a datetime using `timestamp_format`. This is useful when the format cannot match perfectly what is returned by Elasticsearch. When set, this option is evaluated as a Python expression along with a *globals* dictionary containing the original timestamp to be refined (as a string) named `ts`. The returned value will be parse into a python datetime using the previously defined format (or using the default `'%Y-%m-%dT%H:%M:%SZ'`).

For example, when the date type field returned by Elasticsearch uses nanoseconds (`yyyy-MM-dd'T'HH:mm:ss.SSS.XXXXXX`) and `timestamp_format` option is `'%Y-%m-%dT%H:%M:%S.%f'` (ns are not supported in python `datetime.datetime.strptime`), Elasticsearch would fail to parse the timestamp terms as they contain nanoseconds values - that is it gets 3 additional digits that can't be parsed, throwing the exception `ValueError: unconverted data remains: XXX``. Setting `timestamp_to_datetime_format_expr: 'ts[:23]'` will truncate the value to milliseconds, allowing a good conversion in a datetime object. This option is only valid if `timestamp_type` set to `custom`. (Optional, string, no default).

### **`_source_enabled`**

`_source_enabled`: If true, ElastAlert 2 will use `_source` to retrieve fields from documents in Elasticsearch. If false, ElastAlert 2 will use `fields` to retrieve stored fields. Both of these are represented internally as if they came from `_source`. See <https://www.elastic.co/guide/en/elasticsearch/reference/current/mapping-fields.html> for more details. The fields used come from `include`, see above for more details. (Optional, boolean, default True)

### **`scan_entire_timeframe`**

`scan_entire_timeframe`: If true, when ElastAlert 2 starts, it will always start querying at the current time minus the timeframe. `timeframe` must exist in the rule. This may be useful, for example, if you are using a flatline rule type with a large timeframe, and you want to be sure that if ElastAlert 2 restarts, you can still get alerts. This may cause duplicate alerts for some rule types, for example, Frequency can alert multiple times in a single timeframe, and if ElastAlert 2 were to restart with this setting, it may scan the same range again, triggering duplicate alerts.

Some rules and alerts require additional options, which also go in the top level of the rule configuration file.

### **`query_timezone`**

`query_timezone`: Whether to convert UTC time to the specified time zone in rule queries. If not set, start and end time of query will be used UTC. (Optional, string, default empty string)

Example value : `query_timezone: "Europe/Istanbul"`

## **5.3 Testing Your Rule**

Once you've written a rule configuration, you will want to validate it. To do so, you can either run ElastAlert 2 in debug mode, or use `elastalert-test-rule`, which is a script that makes various aspects of testing easier.

It can:

- Check that the configuration file loaded successfully.
- Check that the Elasticsearch filter parses.
- Run against the last X day(s) and show the number of hits that match your filter.
- Show the available terms in one of the results.
- Save documents returned to a JSON file.
- Run ElastAlert 2 using either a JSON file or actual results from Elasticsearch.
- Print out debug alerts or trigger real alerts.
- Check that, if they exist, the `primary_key`, `compare_key` and `include` terms are in the results.
- Show what metadata documents would be written to `elastalert_status`.

Without any optional arguments, it will run ElastAlert 2 over the last 24 hours and print out any alerts that would have occurred. Here is an example test run which triggered an alert:

```
$ elastalert-test-rule my_rules/rule1.yaml
Successfully Loaded Example rule1

Got 105 hits from the last 1 day
```

(continues on next page)

(continued from previous page)

```

Available terms in first hit:
  @timestamp
  field1
  field2
  ...
Included term this_field_doesnt_exist may be missing or null

INFO:root:Queried rule Example rule1 from 6-16 15:21 PDT to 6-17 15:21 PDT: 105 hits
INFO:root:Alert for Example rule1 at 2015-06-16T23:53:12Z:
INFO:root:Example rule1

At least 50 events occurred between 6-16 18:30 PDT and 6-16 20:30 PDT

field1:
value1: 25
value2: 25

@timestamp: 2015-06-16T20:30:04-07:00
field1: value1
field2: something

Would have written the following documents to elasticsearch_status:

silence - {'rule_name': 'Example rule1', '@timestamp': datetime.datetime( ... ),
  ↳ 'exponent': 0, 'until':
  datetime.datetime( ... )}

elasticsearch_status - {'hits': 105, 'matches': 1, '@timestamp': datetime.datetime( ... ),
  ↳ 'rule_name': 'Example rule1',
  'starttime': datetime.datetime( ... ), 'endtime': datetime.datetime( ... ), 'time_taken
  ↳ ': 3.1415926}

```

Note that Docker users can also run the test tool:

```

$ docker run --rm -it --net es_default \
  -v $(pwd)/elastalert.yaml:/opt/elastalert/config.yaml \
  -v $(pwd)/rules:/opt/elastalert/rules \
  --entrypoint elastalert-test-rule \
  jertel/elastalert2 \
  /opt/elastalert/rules/example_frequency.yaml

```

If you want to specify an alternate configuration file to use, you can add the config flag prior to the rule filename:

```
--config <path-to-config-file>
```

**The configuration preferences will be loaded as follows:**

1. Configurations specified in the yaml file.
2. Configurations specified in the config file, if specified.
3. Default configurations, for the tool to run.

Note that everything between “Alert for Example rule1 at ...” and “Would have written the following ...” is the exact

text body that an alert would have. See the section below on alert content for more details. Also note that datetime objects are converted to ISO8601 timestamps when uploaded to Elasticsearch. See [the section on metadata](#) for more details.

Other options include:

`--schema-only`: Only perform schema validation on the file. It will not load modules or query Elasticsearch. This may catch invalid YAML and missing or misconfigured fields.

`--count-only`: Only find the number of matching documents and list available fields. ElastAlert 2 will not be run and documents will not be downloaded.

`--days N`: Instead of the default 1 day, query N days. For selecting more specific time ranges, use `--start` and `--end`.

`--start <timestamp>` The starting date/time of the search filter's time range. The timestamp is formatted as YYYY-MM-DDTHH:MM:SS (UTC) or with timezone YYYY-MM-DDTHH:MM:SS-XX:00 (UTC-XX). If `timeframe` is specified, defaults to the ending time - timeframe. Otherwise defaults to ending time - 1 day.

`--end <timestamp>` The ending date/time of the search filter's time range. The timestamp is formatted as YYYY-MM-DDTHH:MM:SS (UTC) or with timezone YYYY-MM-DDTHH:MM:SS-XX:00 (UTC-XX). Defaults to the current time.

`--save-json FILE`: Save all documents downloaded to a file as JSON. This is useful if you wish to modify data while testing or do offline testing in conjunction with `--data FILE`. A maximum of 10,000 documents will be downloaded.

`--data FILE`: Use a JSON file as a data source instead of Elasticsearch. The file should be a single list containing objects, rather than objects on separate lines. Note that this uses mock functions which mimic some Elasticsearch query methods and is not guaranteed to have the exact same results as with Elasticsearch. For example, analyzed string fields may behave differently.

`--alert`: Trigger real alerts instead of the debug (logging text) alert.

`--formatted-output`: Output results in formatted JSON.

---

**Note:** Results from running this script may not always be the same as if an actual ElastAlert 2 instance was running. Some rule types, such as spike and flatline require a minimum elapsed time before they begin alerting, based on their timeframe. In addition, `use_count_query` and `use_terms_query` rely on `run_every` to determine their resolution. This script uses a fixed 5 minute window, which is the same as the default.

Also, EQL filters do not support counts, so the output relating to counts may show N/A (Not Applicable).

---

## 5.4 Rule Types

The various `RuleType` classes, defined in `elastalert/ruletypes.py`, form the main logic behind ElastAlert 2. An instance is held in memory for each rule, passed all of the data returned by querying Elasticsearch with a given filter, and generates matches based on that data.

To select a rule type, set the `type` option to the name of the rule type in the rule configuration file:

`type: <rule type>`

### 5.4.1 Any

**any:** The any rule will match everything. Every hit that the query returns will generate an alert.

### 5.4.2 Blacklist

**blacklist:** The blacklist rule will check a certain field against a blacklist, and match if it is in the blacklist.

This rule requires two additional options:

**compare\_key:** The name of the field to use to compare to the blacklist. If the field is null, those events will be ignored.

**blacklist:** A list of blacklisted values, and/or a list of paths to flat files which contain the blacklisted values using - `"!file /path/to/file"`; for example:

```
blacklist:
- value1
- value2
- "!file /tmp/blacklist1.txt"
- "!file /tmp/blacklist2.txt"
```

It is possible to mix between blacklist value definitions, or use either one. The `compare_key` term must be equal to one of these values for it to match.

### 5.4.3 Whitelist

**whitelist:** Similar to `blacklist`, this rule will compare a certain field to a whitelist, and match if the list does not contain the term.

This rule requires three additional options:

**compare\_key:** The name of the field to use to compare to the whitelist.

**ignore\_null:** If true, events without a `compare_key` field will not match.

**whitelist:** A list of whitelisted values, and/or a list of paths to flat files which contain the whitelisted values using - `"!file /path/to/file"`; for example:

```
whitelist:
- value1
- value2
- "!file /tmp/whitelist1.txt"
- "!file /tmp/whitelist2.txt"
```

It is possible to mix between whitelisted value definitions, or use either one. The `compare_key` term must be in this list or else it will match.

### 5.4.4 Change

For an example configuration file using this rule type, look at `examples/rules/example_change.yaml`.

**change:** This rule will monitor a certain field and match if that field changes. The field must change with respect to the last event with the same `query_key`.

This rule requires three additional options:

**compare\_key:** The names of the field to monitor for changes. Since this is a list of strings, we can have multiple keys. An alert will trigger if any of the fields change.

**ignore\_null:** If true, events without a `compare_key` field will not count as changed. Currently this checks for all the fields in `compare_key`

**query\_key:** This rule is applied on a per-`query_key` basis. This field must be present in all of the events that are checked.

There is also an optional field:

**timeframe:** The maximum time between changes. After this time period, ElastAlert 2 will forget the old value of the `compare_key` field.

### 5.4.5 Frequency

For an example configuration file using this rule type, look at `examples/rules/example_frequency.yaml`.

**frequency:** This rule matches when there are at least a certain number of events in a given time frame. This may be counted on a per-`query_key` basis.

This rule requires two additional options:

**num\_events:** The number of events which will trigger an alert, inclusive.

**timeframe:** The time that `num_events` must occur within.

Optional:

**use\_count\_query:** If true, ElastAlert 2 will poll Elasticsearch using the count api, and not download all of the matching documents. This is useful if you care only about numbers and not the actual data. It should also be used if you expect a large number of query hits, in the order of tens of thousands or more.

**use\_terms\_query:** If true, ElastAlert 2 will make an aggregation query against Elasticsearch to get counts of documents matching each unique value of `query_key`. This must be used with `query_key`. This will only return a maximum of `terms_size`, default 50, unique terms.

**terms\_size:** When used with `use_terms_query`, this is the maximum number of terms returned per query. Default is 50.

**query\_key:** Counts of documents will be stored independently for each value of `query_key`. Only `num_events` documents, all with the same value of `query_key`, will trigger an alert.

**attach\_related:** Will attach all the related events to the event that triggered the frequency alert. For example in an alert triggered with `num_events: 3`, the 3rd event will trigger the alert on itself and add the other 2 events in a key named `related_events` that can be accessed in the alerter.

### 5.4.6 Spike

**spike:** This rule matches when the volume of events during a given time period is `spike_height` times larger or smaller than during the previous time period. It uses two sliding windows to compare the current and reference frequency of events. We will call this two windows “reference” and “current”.

This rule requires three additional options:

**spike\_height:** The ratio of number of events in the last `timeframe` to the previous `timeframe` that when hit will trigger an alert.

**spike\_type:** Either ‘up’, ‘down’ or ‘both’. ‘Up’ meaning the rule will only match when the number of events is `spike_height` times higher. ‘Down’ meaning the reference number is `spike_height` higher than the current number. ‘Both’ will match either.

**timeframe:** The rule will average out the rate of events over this time period. For example, `hours: 1` means that the ‘current’ window will span from present to one hour ago, and the ‘reference’ window will span from one hour ago to two hours ago. The rule will not be active until the time elapsed from the first event is at least two timeframes. This is to prevent an alert being triggered before a baseline rate has been established. This can be overridden using `alert_on_new_data`, provided the rule uses the `query_key` property (see more information on this below).

Optional:

**field\_value:** When set, uses the value of the field in the document and not the number of matching documents. This is useful to monitor for example a temperature sensor and raise an alarm if the temperature grows too fast. Note that the means of the field on the reference and current windows are used to determine if the `spike_height` value is reached. Note also that the threshold parameters are ignored in this mode.

**threshold\_ref:** The minimum number of events that must exist in the reference window for an alert to trigger. For example, if `spike_height: 3` and `threshold_ref: 10`, then the ‘reference’ window must contain at least 10 events and the ‘current’ window at least three times that for an alert to be triggered.

**threshold\_cur:** The minimum number of events that must exist in the current window for an alert to trigger. For example, if `spike_height: 3` and `threshold_cur: 60`, then an alert will occur if the current window has more than 60 events and the reference window has less than a third as many.

To illustrate the use of `threshold_ref`, `threshold_cur`, `alert_on_new_data`, `timeframe` and `spike_height` together, consider the following examples:

```
" Alert if at least 15 events occur within two hours and less than a quarter of that
↳ number occurred within the previous two hours. "
timeframe: hours: 2
spike_height: 4
spike_type: up
threshold_cur: 15

hour1: 5 events (ref: 0, cur: 5) - No alert because (a) threshold_cur not met, (b) ref_
↳ window not filled
hour2: 5 events (ref: 0, cur: 10) - No alert because (a) threshold_cur not met, (b) ref_
↳ window not filled
hour3: 10 events (ref: 5, cur: 15) - No alert because (a) spike_height not met, (b) ref_
↳ window not filled
hour4: 35 events (ref: 10, cur: 45) - Alert because (a) spike_height met, (b) threshold_
↳ cur met, (c) ref window filled

hour5: 200 events (ref: 60, cur: 280) - No alert because spike_height not met

```

**alert\_on\_new\_data:** This option is only used if **query\_key** is set. When this is set to true, any new **query\_key** encountered may trigger an immediate alert. When set to false, baseline must be established for each new **query\_key** value, and then subsequent spikes may cause alerts. Baseline is established after **timeframe** has elapsed twice since first occurrence.

**use\_count\_query:** If true, ElastAlert 2 will poll Elasticsearch using the count api, and not download all of the matching documents. This is useful if you care only about numbers and not the actual data. It should also be used if you expect a large number of query hits, in the order of tens of thousands or more.

**use\_terms\_query:** If true, ElastAlert 2 will make an aggregation query against Elasticsearch to get counts of documents matching each unique value of **query\_key**. This must be used with **query\_key**. This will only return a maximum of **terms\_size**, default 50, unique terms.

**terms\_size:** When used with **use\_terms\_query**, this is the maximum number of terms returned per query. Default is 50.

**query\_key:** Counts of documents will be stored independently for each value of **query\_key**.

### 5.4.7 Flatline

**flatline:** This rule matches when the total number of events is under a given **threshold** for a time period.

This rule requires two additional options:

**threshold:** The minimum number of events for an alert not to be triggered.

**timeframe:** The time period that must contain less than **threshold** events.

Optional:

**use\_count\_query:** If true, ElastAlert 2 will poll Elasticsearch using the count api, and not download all of the matching documents. This is useful if you care only about numbers and not the actual data. It should also be used if you expect a large number of query hits, in the order of tens of thousands or more.

**use\_terms\_query:** If true, ElastAlert 2 will make an aggregation query against Elasticsearch to get counts of documents matching each unique value of **query\_key**. This must be used with **query\_key**. This will only return a maximum of **terms\_size**, default 50, unique terms.

**terms\_size:** When used with **use\_terms\_query**, this is the maximum number of terms returned per query. Default is 50.

**query\_key:** With flatline rule, **query\_key** means that an alert will be triggered if any value of **query\_key** has been seen at least once and then falls below the threshold. To reference the **query\_key** value within a flatline alert message, use **key** as the field name.

**forget\_keys:** Only valid when used with **query\_key**. If this is set to true, ElastAlert 2 will “forget” about the **query\_key** value that triggers an alert, therefore preventing any more alerts for it until it’s seen again.

### 5.4.8 New Term

**new\_term:** This rule matches when a new value appears in a field that has never been seen before. When ElastAlert 2 starts, it will use an aggregation query to gather all known terms for a list of fields.

This rule requires one additional option:

**fields:** A list of fields to monitor for new terms. **query\_key** will be used if **fields** is not set. Each entry in the list of fields can itself be a list. If a field entry is provided as a list, it will be interpreted as a set of fields that compose a composite key used for the ElasticSearch query.

---

**Note:** The composite fields may only refer to primitive types, otherwise the initial ElasticSearch query will not properly return the aggregation results, thus causing alerts to fire every time the ElastAlert 2 service initially launches with the rule. A warning will be logged to the console if this scenario is encountered. However, future alerts will actually work as expected after the initial flurry.

---

Optional:

**terms\_window\_size:** The amount of time used for the initial query to find existing terms. No term that has occurred within this time frame will trigger an alert. The default is 30 days.

**window\_step\_size:** When querying for existing terms, split up the time range into steps of this size. For example, using the default 30 day window size, and the default 1 day step size, 30 individual queries will be made. This helps to avoid timeouts for very expensive aggregation queries. The default is 1 day.

**alert\_on\_missing\_field:** Whether or not to alert when a field is missing from a document. The default is false.

**use\_terms\_query:** If true, ElastAlert 2 will use aggregation queries to get terms instead of regular search queries. This is faster than regular searching if there is a large number of documents. If this is used, you may only specify a

single field, and must also set `query_key` to that field. Also, note that `terms_size` (the number of buckets returned per query) defaults to 50. This means that if a new term appears but there are at least 50 terms which appear more frequently, it will not be found.

---

**Note:** When using `use_terms_query`, make sure that the field you are using is not analyzed. If it is, the results of each terms query may return tokens rather than full values. ElastAlert 2 will by default turn on `use_keyword_postfix`, which attempts to use the non-analyzed version (`.keyword`) to gather initial terms. These will not match the partial values and result in false positives.

---

`use_keyword_postfix`: If true, ElastAlert 2 will automatically try to add `.keyword` to the fields when making an initial query. These are non-analyzed fields added by Logstash. If the field used is analyzed, the initial query will return only the tokenized values, potentially causing false positives. Defaults to true.

### 5.4.9 Cardinality

`cardinality`: This rule matches when a the total number of unique values for a certain field within a time frame is higher or lower than a threshold.

This rule requires:

`timeframe`: The time period in which the number of unique values will be counted.

`cardinality_field`: Which field to count the cardinality for.

This rule requires one of the two following options:

`max_cardinality`: If the cardinality of the data is greater than this number, an alert will be triggered. Each new event that raises the cardinality will trigger an alert.

`min_cardinality`: If the cardinality of the data is lower than this number, an alert will be triggered. The `timeframe` must have elapsed since the first event before any alerts will be sent. When a match occurs, the `timeframe` will be reset and must elapse again before additional alerts.

Optional:

`query_key`: Group cardinality counts by this field. For each unique value of the `query_key` field, cardinality will be counted separately.

### 5.4.10 Metric Aggregation

`metric_aggregation`: This rule matches when the value of a metric within the calculation window is higher or lower than a threshold. By default this is `buffer_time`.

This rule requires:

`metric_agg_key`: This is the name of the field over which the metric value will be calculated. The underlying type of this field must be supported by the specified aggregation type. If using a scripted field via `metric_agg_script`, this is the name for your scripted field

`metric_agg_type`: The type of metric aggregation to perform on the `metric_agg_key` field. This must be one of 'min', 'max', 'avg', 'sum', 'cardinality', 'value\_count', 'percentiles'. Note, if *percentiles* is used, then `percentile_range` must also be specified.

---

**Note:** When Metric Aggregation has a match, `match_body` includes an aggregated value that triggered the match so that you can use that on an alert. The value is named based on `metric_agg_key` and `metric_agg_type`. For example, if you set `metric_agg_key` to 'system.cpu.total.norm.pct' and `metric_agg_type` to 'avg', the name of the value is

---

`'metric_system.cpu.total.norm.pct_avg'`. Because of this naming rule, you might face conflicts with jinja2 template, and when that happens, you also can use `'metric_agg_value'` from `match_body` instead.

---

This rule also requires at least one of the two following options:

**max\_threshold:** If the calculated metric value is greater than this number, an alert will be triggered. This threshold is exclusive.

**min\_threshold:** If the calculated metric value is less than this number, an alert will be triggered. This threshold is exclusive.

**percentile\_range:** An integer specifying the percentage value to aggregate against. Must be specified if **metric\_agg\_type** is set to **percentiles**. See <https://www.elastic.co/guide/en/elasticsearch/reference/current/search-aggregations-metrics-percentile-aggregation.html> for more information.

Optional:

**query\_key:** Group metric calculations by this field. For each unique value of the **query\_key** field, the metric will be calculated and evaluated separately against the threshold(s).

**metric\_agg\_script:** A *Painless* formatted script describing how to calculate your metric on-the-fly:

```
metric_agg_key: myScriptedMetric
metric_agg_script:
  script: doc['field1'].value * doc['field2'].value
```

**min\_doc\_count:** The minimum number of events in the current window needed for an alert to trigger. Used in conjunction with **query\_key**, this will only consider terms which in their last **buffer\_time** had at least **min\_doc\_count** records. Default 1.

**use\_run\_every\_query\_size:** By default the metric value is calculated over a **buffer\_time** sized window. If this parameter is true the rule will use **run\_every** as the calculation window.

**allow\_buffer\_time\_overlap:** This setting will only have an effect if **use\_run\_every\_query\_size** is false and **buffer\_time** is greater than **run\_every**. If true will allow the start of the metric calculation window to overlap the end time of a previous run. By default the start and end times will not overlap, so if the time elapsed since the last run is less than the metric calculation window size, rule execution will be skipped (to avoid calculations on partial data).

**bucket\_interval:** If present this will divide the metric calculation window into **bucket\_interval** sized segments. The metric value will be calculated and evaluated against the threshold(s) for each segment. If **bucket\_interval** is specified then **buffer\_time** must be a multiple of **bucket\_interval**. (Or **run\_every** if **use\_run\_every\_query\_size** is true).

**sync\_bucket\_interval:** This only has an effect if **bucket\_interval** is present. If true it will sync the start and end times of the metric calculation window to the keys (timestamps) of the underlying **date\_histogram** buckets. Because of the way elasticsearch calculates **date\_histogram** bucket keys these usually round evenly to nearest minute, hour, day etc (depending on the bucket size). By default the bucket keys are offset to align with the time ElastAlert 2 runs, (This both avoid calculations on partial data, and ensures the very latest documents are included). See: [https://www.elastic.co/guide/en/elasticsearch/reference/current/search-aggregations-bucket-datehistogram-aggregation.html#\\_offset](https://www.elastic.co/guide/en/elasticsearch/reference/current/search-aggregations-bucket-datehistogram-aggregation.html#_offset) for a more comprehensive explanation.

**metric\_format\_string:** An optional format string applies to the aggregated metric value in the alert match text and **match\_body**. This adds `'metric_{metric_agg_key}_formatted'` value to the **match\_body** in addition to raw, unformatted `'metric_{metric_agg_key}'` value so that you can use the values for **alert\_subject\_args** and **alert\_text\_args**. Must be a valid python format string. Both `str.format()` and `%-format` syntax works. For example, `"{:2%}"` will format `'0.966666667'` to `'96.67%'`, and `"%.2f"` will format `'0.966666667'` to `'0.97'`. See: <https://docs.python.org/3.4/library/string.html#format-specification-mini-language>

### 5.4.11 Spike Aggregation

**spike\_aggregation:** This rule matches when the value of a metric within the calculation window is **spike\_height** times larger or smaller than during the previous time period. It uses two sliding windows to compare the current and reference metric values. We will call these two windows “reference” and “current”.

This rule requires:

**metric\_agg\_key:** This is the name of the field over which the metric value will be calculated. The underlying type of this field must be supported by the specified aggregation type. If using a scripted field via **metric\_agg\_script**, this is the name for your scripted field

**metric\_agg\_type:** The type of metric aggregation to perform on the **metric\_agg\_key** field. This must be one of ‘min’, ‘max’, ‘avg’, ‘sum’, ‘cardinality’, ‘value\_count’, ‘percentiles’. Note, if *percentiles* is used, then **percentile\_range** must also be specified.

**spike\_height:** The ratio of the metric value in the last **timeframe** to the previous **timeframe** that when hit will trigger an alert.

**spike\_type:** Either ‘up’, ‘down’ or ‘both’. ‘Up’ meaning the rule will only match when the metric value is **spike\_height** times higher. ‘Down’ meaning the reference metric value is **spike\_height** higher than the current metric value. ‘Both’ will match either.

**buffer\_time:** The rule will average out the rate of events over this time period. For example, **hours: 1** means that the ‘current’ window will span from present to one hour ago, and the ‘reference’ window will span from one hour ago to two hours ago. The rule will not be active until the time elapsed from the first event is at least two timeframes. This is to prevent an alert being triggered before a baseline rate has been established. This can be overridden using **alert\_on\_new\_data**.

**percentile\_range:** An integer specifying the percentage value to aggregate against. Must be specified if **metric\_agg\_type** is set to **percentiles**. See <https://www.elastic.co/guide/en/elasticsearch/reference/current/search-aggregations-metrics-percentile-aggregation.html> for more information.

Optional:

**query\_key:** Group metric calculations by this field. For each unique value of the **query\_key** field, the metric will be calculated and evaluated separately against the ‘reference’/‘current’ metric value and **spike height**.

**metric\_agg\_script:** A *Painless* formatted script describing how to calculate your metric on-the-fly:

```
metric_agg_key: myScriptedMetric
metric_agg_script:
  script: doc['field1'].value * doc['field2'].value
```

**threshold\_ref:** The minimum value of the metric in the reference window for an alert to trigger. For example, if **spike\_height: 3** and **threshold\_ref: 10**, then the ‘reference’ window must have a metric value of 10 and the ‘current’ window at least three times that for an alert to be triggered.

**threshold\_cur:** The minimum value of the metric in the current window for an alert to trigger. For example, if **spike\_height: 3** and **threshold\_cur: 60**, then an alert will occur if the current window has a metric value greater than 60 and the reference window is less than a third of that value.

**min\_doc\_count:** The minimum number of events in the current window needed for an alert to trigger. Used in conjunction with **query\_key**, this will only consider terms which in their last **buffer\_time** had at least **min\_doc\_count** records. Default 1.

### 5.4.12 Percentage Match

**percentage\_match:** This rule matches when the percentage of document in the match bucket within a calculation window is higher or lower than a threshold. By default the calculation window is `buffer_time`.

This rule requires:

**match\_bucket\_filter:** ES filter DSL. This defines a filter for the match bucket, which should match a subset of the documents returned by the main query filter.

This rule also requires at least one of the two following options:

**min\_percentage:** If the percentage of matching documents is less than this number, an alert will be triggered.

**max\_percentage:** If the percentage of matching documents is greater than this number, an alert will be triggered.

Optional:

**query\_key:** Group percentage by this field. For each unique value of the `query_key` field, the percentage will be calculated and evaluated separately against the threshold(s).

**use\_run\_every\_query\_size:** See `use_run_every_query_size` in Metric Aggregation rule

**allow\_buffer\_time\_overlap:** See `allow_buffer_time_overlap` in Metric Aggregation rule

**bucket\_interval:** See `bucket_interval` in Metric Aggregation rule

**sync\_bucket\_interval:** See `sync_bucket_interval` in Metric Aggregation rule

**percentage\_format\_string:** An optional format string applies to the percentage value in the alert match text and `match_body`. This adds `'percentage_formatted'` value to the `match_body` in addition to raw, unformatted `'percentage'` value so that you can use the values for `alert_subject_args` and `alert_text_args`. Must be a valid python format string. Both `str.format()` and `%-format` syntax works. For example, both `"{:.2f}"` and `"%.2f"` will format `'96.6666667'` to `'96.67'`. See: <https://docs.python.org/3.4/library/string.html#format-specification-mini-language>

**min\_denominator:** Minimum number of documents on which percentage calculation will apply. Default is 0.

## ALERTS

Each rule may have any number of alerts attached to it. Alerts are subclasses of `Alert` and are passed a dictionary, or list of dictionaries, from ElastAlert 2 which contain relevant information. They are configured in the rule configuration file similarly to rule types.

To set the alerts for a rule, set the `alert` option to the name of the alert, or a list of the names of alerts:

```
alert: email
```

or

```
alert:
- alerta
- alertmanager
- chatwork
- command
- datadog
- debug
- dingtalk
- discord
- email
- exotel
- gitter
- googlechat
- gelf
- hivealerter
- iris
- jira
- lark
- linenotify
- mattermost
- ms_teams
- opsgenie
- pagerduty
- pagertree
- post
- post2
- rocketchat
- servicenow
- ses
- slack
- sns
- stomp
```

(continues on next page)

(continued from previous page)

```
- telegram
- tencent_sms
- twilio
- victorops
- workwechat
- zabbix
```

Options for each alerter can either be defined at the top level of the YAML file, or nested within the alert name, allowing for different settings for multiple of the same alerter. For example, consider sending multiple emails, but with different ‘To’ and ‘From’ fields:

```
alert:
- email
from_addr: "no-reply@example.com"
email: "customer@example.com"
```

versus

```
alert:
- email:
    from_addr: "no-reply@example.com"
    email: "customer@example.com"
- email:
    from_addr: "elastalert@example.com"
    email: "devs@example.com"
```

If multiple of the same alerter type are used, top level settings will be used as the default and inline settings will override those for each alerter.

## 6.1 Alert Subject

E-mail subjects, Jira issue summaries, PagerDuty alerts, or any alerter that has a “subject” can be customized by adding an `alert_subject` that contains a custom summary. It can be further formatted using standard Python formatting syntax:

```
alert_subject: "Issue {0} occurred at {1}"
```

The arguments for the formatter will be fed from the matched objects related to the alert. The field names whose values will be used as the arguments can be passed with `alert_subject_args`:

```
alert_subject_args:
- issue.name
- "@timestamp"
```

It is mandatory to enclose the `@timestamp` field in quotes since in YAML format a token cannot begin with the `@` character. Not using the quotation marks will trigger a YAML parse error.

In case the rule matches multiple objects in the index, only the first match is used to populate the arguments for the formatter.

If the field(s) mentioned in the arguments list are missing, the email alert will have the text `alert_missing_value` in place of its expected value. This will also occur if `use_count_query` is set to true.

## 6.2 Alert Content

There are several ways to format the body text of the various types of events. In EBNF:

```
rule_name      = name
alert_text     = alert_text
ruletype_text  = Depends on type
top_counts_header = top_count_key, ":"
top_counts_value = Value, ":", Count
top_counts     = top_counts_header, LF, top_counts_value
field_values   = Field, ":", Value
```

Similarly to `alert_subject`, `alert_text` can be further formatted using Jinja2 Templates or Standard Python Formatting Syntax

### 1. Jinja Template

By setting `alert_text_type: alert_text_jinja` you can use jinja2 templates in `alert_text` and `alert_subject`.

```
alert_text_type: alert_text_jinja

alert_text: |
    Alert triggered! *({{num_hits}} Matches!)*
    Something happened with {{username}} ({{email}})
    {{description|truncate}}
```

Top fields are accessible via `{{field_name}}` or `{{_data['field_name']}}`, `_data` is useful when accessing *fields with dots in their keys*, as Jinja treat dot as a nested field. If `_data` conflicts with your top level data, use `jinja_root_name` to change its name.

### 2. Standard Python Formatting Syntax

The field names whose values will be used as the arguments can be passed with `alert_text_args` or `alert_text_kw`. You may also refer to any top-level rule property in the `alert_subject_args`, `alert_text_args`, `alert_missing_value`, and `alert_text_kw` fields. However, if the matched document has a key with the same name, that will take preference over the rule property.

```
alert_text: "Something happened with {0} at {1}"
alert_text_type: alert_text_only
alert_text_args: ["username", "@timestamp"]
```

By default:

```
body      = rule_name

          [alert_text]

          ruletype_text

          {top_counts}

          {field_values}
```

With `alert_text_type: alert_text_only`:

```
body                = rule_name

                    alert_text
```

With `alert_text_type: alert_text_jinja:`

```
body                = rule_name

                    alert_text
```

With `alert_text_type: exclude_fields:`

```
body                = rule_name

                    [alert_text]

                    ruletype_text

                    {top_counts}
```

With `alert_text_type: aggregation_summary_only:`

```
body                = rule_name

                    aggregation_summary
```

`ruletype_text` is the string returned by `RuleType.get_match_str`.

`field_values` will contain every key value pair included in the results from Elasticsearch. These fields include “@timestamp” (or the value of `timestamp_field`), every key in `include`, every key in `top_count_keys`, `query_key`, and `compare_key`. If the alert spans multiple events, these values may come from an individual event, usually the one which triggers the alert.

When using `alert_text_args`, you can access nested fields and index into arrays. For example, if your match was `{"data": {"ips": ["127.0.0.1", "12.34.56.78"]}}`, then by using `"data.ips[1]"` in `alert_text_args`, it would replace value with `"12.34.56.78"`. This can go arbitrarily deep into fields and will still work on keys that contain dots themselves.

Further, accessing subfields within a nested array structure is accomplished by specifying the subfield name directly after the array index brackets.

For example, given the below data:

```
{"data": { "items": [{ "name": "Mickey Mouse", "price": 24.95 }, { "name": "Winnie the_
↪Pooh", "price": 14.95 }], "tax": 2.39, "total": 42.29 } }
```

You would then access the fields as follows:

```
data.items[0]name
data.items[0]price
data.items[1]name
data.items[1]price
data.tax
data.total
```

## 6.3 Alerter Base Type

For all Alerter subclasses, you may reference values from a top-level rule property in your Alerter fields by referring to the property name surrounded by dollar signs. This can be useful when you have rule-level properties that you would like to reference many times in your alert. For example:

Example usage:

```
jira_priority: $priority$
jira_alert_owner: $owner$
```

## 6.4 Alert Types

### 6.4.1 Alerta

Alerta alerter will post an alert in the Alerta server instance through the alert API endpoint. See <https://docs.alerta.io/api/reference.html#alerts> for more details on the Alerta JSON format.

For Alerta 5.0

Required:

`alerta_api_url`: API server URL.

Optional:

`alerta_api_key`: This is the api key for alerta server, sent in an `Authorization` HTTP header. If not defined, no `Authorization` header is sent.

`alerta_use_qk_as_resource`: If true and `query_key` is present, this will override `alerta_resource` field with the `query_key` value (Can be useful if `query_key` is a hostname).

`alerta_use_match_timestamp`: If true, it will use the timestamp of the first match as the `createTime` of the alert. otherwise, the current server time is used.

`alerta_api_skip_ssl`: Defaults to False.

`alert_missing_value`: Text to replace any match field not found when forming strings. Defaults to `<MISSING_TEXT>`.

The following options dictate the values of the API JSON payload:

`alerta_severity`: Defaults to “warning”.

`alerta_timeout`: Defaults 84600 (1 Day).

`alerta_type`: Defaults to “elastalert”.

The following options use Python-like string syntax `{<field>}` or `%(<field>)s` to access parts of the match, similar to the `CommandAlerter`. Ie: “Alert for {clientip}”. If the referenced key is not found in the match, it is replaced by the text indicated by the option `alert_missing_value`.

`alerta_resource`: Defaults to “elastalert”.

`alerta_service`: Defaults to “elastalert”.

`alerta_origin`: Defaults to “elastalert”.

`alerta_environment`: Defaults to “Production”.

`alerta_group`: Defaults to “”.

alerta\_correlate: Defaults to an empty list.

alerta\_tags: Defaults to an empty list.

alerta\_event: Defaults to the rule's name.

alerta\_text: Defaults to the rule's text according to its type.

alerta\_value: Defaults to "".

The `attributes` dictionary is built by joining the lists from `alerta_attributes_keys` and `alerta_attributes_values`, considered in order.

Example usage using old-style format:

```
alert:
  - alerta
alerta_api_url: "http://youralertahost/api/alert"
alerta_attributes_keys: ["hostname", "TimestampEvent", "senderIP" ]
alerta_attributes_values: ["%(key)s", "%(logdate)s", "%(sender_ip)s" ]
alerta_correlate: ["ProbeUP", "ProbeDOWN"]
alerta_event: "ProbeUP"
alerta_text: "Probe %(hostname)s is UP at %(logdate)s GMT"
alerta_value: "UP"
```

Example usage using new-style format:

```
alert:
  - alerta
alerta_attributes_values: ["{key}", "{logdate}", "{sender_ip}" ]
alerta_text: "Probe {hostname} is UP at {logdate} GMT"
```

## 6.4.2 Alertmanager

This alert type will send alerts to Alertmanager `postAlerts`. `alert_subject` and `alert_text` are passed as the annotations labeled `summary` and `description` accordingly. The labels can be changed. See <https://prometheus.io/docs/alerting/clients/> for more details about the Alertmanager alert format.

Required:

`alertmanager_hosts`: The list of hosts pointing to the Alertmanager.

Optional:

`alertmanager_api_version`: Defaults to `v1`. Set to `v2` to enable the Alertmanager V2 API `postAlerts`.

`alertmanager_alertname`: `alertname` is the only required label. Defaults to using the rule name of the alert.

`alertmanager_labels`: Key:value pairs of arbitrary labels to be attached to every alert. Keys should match the regular expression `^[a-zA-Z_][a-zA-Z0-9_]*$`.

`alertmanager_annotations`: Key:value pairs of arbitrary annotations to be attached to every alert. Keys should match the regular expression `^[a-zA-Z_][a-zA-Z0-9_]*$`.

`alertmanager_fields`: Key:value pairs of labels and corresponding match fields. When using `alertmanager_fields` you can access nested fields and index into arrays the same way as with `alert_text_args`. Keys should match the regular expression `^[a-zA-Z_][a-zA-Z0-9_]*$`. This dictionary will be merged with the `alertmanager_labels`.

`alertmanager_alert_subject_labelname`: Rename the annotations' label name for `alert_subject`. Default is `summary`.

`alertmanager_alert_text_labelname`: Rename the annotations' label name for `alert_text`. Default is `description`.

`alertmanager_proxy`: By default ElastAlert 2 will not use a network proxy to send notifications to Alertmanager. Set this option using `hostname:port` if you need to use a proxy. only supports https.

`alertmanager_ca_certs`: Set this option to `True` or a path to a CA cert bundle or directory (eg: `/etc/ssl/certs/ca-certificates.crt`) to validate the SSL certificate.

`alertmanager_ignore_ssl_errors`: By default ElastAlert 2 will verify SSL certificate. Set this option to `True` if you want to ignore SSL errors.

`alertmanager_timeout`: You can specify a timeout value, in seconds, for making communicating with Alertmanager. The default is 10. If a timeout occurs, the alert will be retried next time ElastAlert 2 cycles. ``

`alertmanager_resolve_time`: Optionally provide an automatic resolution timeframe. If no further alerts arrive within this time period alertmanager will automatically mark the alert as resolved. If not defined it will use Alertmanager's default behavior. `` `alertmanager_basic_auth_login`: Basic authentication username.

`alertmanager_basic_auth_password`: Basic authentication password.

Example usage:

```
alert:
  - "alertmanager"
alertmanager_hosts:
  - "http://alertmanager:9093"
alertmanager_alertname: "Title"
alertmanager_annotations:
  severity: "error"
alertmanager_resolve_time:
  minutes: 10
alertmanager_labels:
  source: "elastalert"
alertmanager_fields:
  msg: "message"
  log: "@log_name"
```

Additional explanation:

ElastAlert 2 can send two categories of data to Alertmanager: labels and annotations

Labels are sent as either static values or a single field value lookup. So if you specify the following:

```
alertmanager_labels:
  someStaticLabel: "Verify this issue"
  anotherStaticLabel: "someone@somewhere.invalid"

alertmanager_fields:
  myLabelName: someElasticFieldName
  anotherLabel: anotherElasticFieldName
```

The first labels will be static, but the two field will be replaced with the corresponding field values from the Elastic record that triggered the alert, and then merged back into the list of labels sent to Alertmanager.

Annotations are slightly different. You can have many static (hardcoded) annotations and only two annotations that will be formatted according to the `alert_text` and `alert_subject` [documentation](<https://elastalert2.readthedocs.io/en/latest/ruletypes.html#alert-subject>).

For example:

```
alertmanager_annotations:
  someStaticAnnotation: "This is a static annotation value, it never changes"
  severity: P3

alertmanager_alert_subject_labelname: myCustomAnnotationName1
alertmanager_alert_text_labelname: myCustomAnnotationName2

alert_subject: "Host {0} has status {1}"
alert_subject_args:
- http_host
- status

alert_text: "URL {0} has {1} matches"
alert_text_type: alert_text_only
alert_text_args:
- uri
- num_matches
```

### 6.4.3 AWS SES (Amazon Simple Email Service)

The AWS SES alerter is similar to Email alerter but uses AWS SES to send emails. The AWS SES alerter can use AWS credentials from the rule yaml, standard AWS config files or environment variables.

AWS SES requires one option:

`ses_email`: An address or list of addresses to sent the alert to.

single address example:

```
ses_email: "one@domain"
```

or

multiple address example:

```
ses_email:
- "one@domain"
- "two@domain"
```

`ses_from_addr`: This sets the From header in the email.

Optional:

`ses_aws_access_key`: An access key to connect to AWS SES with.

`ses_aws_secret_key`: The secret key associated with the access key.

`ses_aws_region`: The AWS region in which the AWS SES resource is located. Default is us-east-1

`ses_aws_profile`: The AWS profile to use. If none specified, the default will be used.

`ses_email_reply_to`: This sets the Reply-To header in the email.

`ses_cc`: This adds the CC emails to the list of recipients. By default, this is left empty.

single address example:

```
ses_cc: "one@domain"
```

or

multiple address example:

```
ses_cc:
- "one@domain"
- "two@domain"
```

ses\_bcc: This adds the BCC emails to the list of recipients but does not show up in the email message. By default, this is left empty.

single address example:

```
ses_bcc: "one@domain"
```

or

multiple address example:

```
ses_bcc:
- "one@domain"
- "two@domain"
```

Example When not using aws\_profile usage:

```
alert:
- "ses"
ses_aws_access_key_id: "XXXXXXXXXXXXXXXXXXXX"
ses_aws_secret_access_key: "YYYYYYYYYYYYYYYYYYYY"
ses_aws_region: "us-east-1"
ses_from_addr: "xxxx1@xxx.com"
ses_email: "xxxx1@xxx.com"
```

Example When to use aws\_profile usage:

```
# Create ~/.aws/credentials

[default]
aws_access_key_id = xxxxxxxxxxxxxxxxxxxx
aws_secret_access_key = yyyyyyyyyyyyyyyyyyyyyyyyyyyyyyyyyy

# Create ~/.aws/config

[default]
region = us-east-1

# alert rule setting

alert:
- "ses"
ses_aws_profile: "default"
ses_from_addr: "xxxx1@xxx.com"
ses_email: "xxxx1@xxx.com"
```

### 6.4.4 AWS SNS (Amazon Simple Notification Service)

The AWS SNS alerter will send an AWS SNS notification. The body of the notification is formatted the same as with other alerters. The AWS SNS alerter uses boto3 and can use credentials in the rule yaml, in a standard AWS credential and config files, or via environment variables. See <http://docs.aws.amazon.com/cli/latest/userguide/cli-chap-getting-started.html> for details.

AWS SNS requires one option:

`sns_topic_arn`: The SNS topic's ARN. For example, `arn:aws:sns:us-east-1:123456789:somesnstopic`

Optional:

`sns_aws_access_key_id`: An access key to connect to SNS with.

`sns_aws_secret_access_key`: The secret key associated with the access key.

`sns_aws_region`: The AWS region in which the SNS resource is located. Default is `us-east-1`

`sns_aws_profile`: The AWS profile to use. If none specified, the default will be used.

Example When not using `aws_profile` usage:

```
alert:
  - sns
sns_topic_arn: 'arn:aws:sns:us-east-1:123456789:somesnstopic'
sns_aws_access_key_id: 'XXXXXXXXXXXXXXXXXXXX'
sns_aws_secret_access_key: 'YYYYYYYYYYYYYYYYYYYY'
sns_aws_region: 'us-east-1' # You must nest aws_region within your alert configuration.
↪so it is not used to sign AWS requests.
```

Example When to use `aws_profile` usage:

```
# Create ~/.aws/credentials

[default]
aws_access_key_id = xxxxxxxxxxxxxxxxxxxxxxxx
aws_secret_access_key = yyyyyyyyyyyyyyyyyyyyyyyyyyyyyyyyyyy

# Create ~/.aws/config

[default]
region = us-east-1

# alert rule setting

alert:
  - sns
sns_topic_arn: 'arn:aws:sns:us-east-1:123456789:somesnstopic'
sns_aws_profile: 'default'
```

### 6.4.5 Chatwork

Chatwork will send notification to a Chatwork application. The body of the notification is formatted the same as with other alerters.

Required:

`chatwork_apikey`: Chatwork API KEY.

`chatwork_room_id`: The ID of the room you are talking to in Chatwork. How to find the room ID is the part of the number after “rid” at the end of the URL of the browser.

`chatwork_proxy`: By default ElastAlert 2 will not use a network proxy to send notifications to Chatwork. Set this option using `hostname:port` if you need to use a proxy. only supports https.

`chatwork_proxy_login`: The Chatwork proxy auth username.

`chatwork_proxy_pass`: The Chatwork proxy auth password.

Example usage:

```
alert:
  - "chatwork"
chatwork_apikey: "xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx"
chatwork_room_id: "xxxxxxxx"
```

### 6.4.6 Command

The command alert allows you to execute an arbitrary command and pass arguments or stdin from the match. Arguments to the command can use Python format string syntax to access parts of the match. The alerter will open a subprocess and optionally pass the match, or matches in the case of an aggregated alert, as a JSON array, to the stdin of the process.

This alert requires one option:

`command`: A list of arguments to execute or a string to execute. If in list format, the first argument is the name of the program to execute. If passed a string, the command is executed through the shell.

Strings can be formatted using the old-style format (%) or the new-style format (`.format()`). When the old-style format is used, fields are accessed using `%(field_name)s`, or `%(field.subfield)s`. When the new-style format is used, fields are accessed using `{field_name}`. New-style formatting allows accessing nested fields (e.g., `{field_1[subfield]}`).

In an aggregated alert, these fields come from the first match.

Optional:

`pipe_match_json`: If true, the match will be converted to JSON and passed to stdin of the command. Note that this will cause ElastAlert 2 to block until the command exits or sends an EOF to stdout.

`pipe_alert_text`: If true, the standard alert body text will be passed to stdin of the command. Note that this will cause ElastAlert 2 to block until the command exits or sends an EOF to stdout. It cannot be used at the same time as `pipe_match_json`.

`fail_on_non_zero_exit`: By default this is False. Allows monitoring of when commands fail to run. When a command returns a non-zero exit status, the alert raises an exception.

Example usage using old-style format:

```
alert:
  - command
command: ["/bin/send_alert", "--username", "%(username)s"]
```

**Warning:** Executing commands with untrusted data can make it vulnerable to shell injection! If you use formatted data in your command, it is highly recommended that you use a args list format instead of a shell string.

Example usage using new-style format:

```
alert:
  - command
command: ["/bin/send_alert", "--username", "{match[username]}"]
```

### 6.4.7 Datadog

This alert will create a [Datadog Event](#). Events are limited to 4000 characters. If an event is sent that contains a message that is longer than 4000 characters, only his first 4000 characters will be displayed.

This alert requires two additional options:

`datadog_api_key`: [Datadog API key](#)

`datadog_app_key`: [Datadog application key](#)

Example usage:

```
alert:
  - "datadog"
datadog_api_key: "Datadog API Key"
datadog_app_key: "Datadog APP Key"
```

### 6.4.8 Debug

The debug alerter will log the alert information using the Python logger at the info level. It is logged into a Python Logger object with the name `elastalert` that can be easily accessed using the `getLogger` command.

### 6.4.9 Dingtalk

Dingtalk will send notification to a Dingtalk application. The body of the notification is formatted the same as with other alerters.

Required:

`dingtalk_access_token`: Dingtalk access token.

`dingtalk_msgtype`: Dingtalk msgtype, default to text. markdown, single\_action\_card, action\_card.

`dingtalk_msgtype` single\_action\_card Required:

`dingtalk_single_title`: The title of a single button..

`dingtalk_single_url`: Jump link for a single button.

`dingtalk_msgtype` action\_card Required:

`dingtalk_btns`: Button.

`dingtalk_msgtype` action\_card Optional:

`dingtalk_btn_orientation`: “0”: Buttons are arranged vertically “1”: Buttons are arranged horizontally.

Example msgtype : text:

```
alert:
  - "dingtalk"
dingtalk_access_token: "xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx"
dingtalk_msgtype: "text"
```

Example msgtype : markdown:

```
alert:
  - "dingtalk"
dingtalk_access_token: "xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx"
dingtalk_msgtype: "markdown"
```

Example msgtype : single\_action\_card:

```
alert:
  - "dingtalk"
dingtalk_access_token: "xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx"
dingtalk_msgtype: "single_action_card"
dingtalk_single_title: "test3"
dingtalk_single_url: "https://xxx.xxx"
```

Example msgtype : action\_card:

```
alert:
  - "dingtalk"
dingtalk_access_token: "xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx"
dingtalk_msgtype: "action_card"
dingtalk_btn_orientation: "0"
dingtalk_btns: [{"title": "a", "actionURL": "https://xxx1.xxx"}, {"title": "b",
↪ "actionURL": "https://xxx2.xxx"}]
```

Optional:

`dingtalk_proxy`: By default ElastAlert 2 will not use a network proxy to send notifications to Dingtalk. Set this option using `hostname:port` if you need to use a proxy. only supports https.

`dingtalk_proxy_login`: The Dingtalk proxy auth username.

`dingtalk_proxy_pass`: The Dingtalk proxy auth username.

## 6.4.10 Discord

Discord will send notification to a Discord application. The body of the notification is formatted the same as with other alerters.

Required:

`discord_webhook_url`: The webhook URL.

Optional:

`discord_emoji_title`: By default ElastAlert 2 will use the `:warning:` emoji when posting to the channel. You can use a different emoji per ElastAlert 2 rule. Any Apple emoji can be used, see <http://emojipedia.org/apple/> . If `discord_embed_icon_url` parameter is provided, emoji is ignored.

`discord_proxy`: By default ElastAlert 2 will not use a network proxy to send notifications to Discord. Set this option using `hostname:port` if you need to use a proxy. only supports https.

`discord_proxy_login`: The Discord proxy auth username.

`discord_proxy_password`: The Discord proxy auth username.

`discord_embed_color`: embed color. By default `0xffffffff`.

`discord_embed_footer`: embed footer.

`discord_embed_icon_url`: You can provide `icon_url` to use custom image. Provide absolute address of the picture.

Example usage:

```
alert:
- "discord"
discord_webhook_url: "Your discord webhook url"
discord_emoji_title: ":lock:"
discord_embed_color: 0xE24D42
discord_embed_footer: "Message sent by from your computer"
discord_embed_icon_url: "https://humancoders-formations.s3.amazonaws.com/uploads/course/
↳ logo/38/thumb_bigger_formation-elasticsearch.png"
```

### 6.4.11 Email

This alert will send an email. It connects to an smtp server located at `smtp_host`, or `localhost` by default. If available, it will use STARTTLS.

This alert requires one additional option:

`email`: An address or list of addresses to sent the alert to.

single address example:

```
email: "one@domain"
```

or

multiple address example:

```
email:
- "one@domain"
- "two@domain"
```

Optional:

`email_from_field`: Use a field from the document that triggered the alert as the recipient. If the field cannot be found, the `email` value will be used as a default. Note that this field will not be available in every rule type, for example, if you have `use_count_query` or if it's type: `flatline`. You can optionally add a domain suffix to the field to generate the address using `email_add_domain`. It can be a single recipient or list of recipients. For example, with the following settings:

```
email_from_field: "data.user"
email_add_domain: "@example.com"
```

and a match `{"@timestamp": "2017", "data": {"foo": "bar", "user": "qlo"}}`

an email would be sent to `qlo@example.com`

`smtp_host`: The SMTP host to use, defaults to localhost.

`smtp_port`: The port to use. Defaults to port 25 when SSL is not used, or 465 when SSL is used.

`smtp_ssl`: Connect the SMTP host using TLS, defaults to `false`. If `smtp_ssl` is not used, ElastAlert 2 will still attempt STARTTLS.

`smtp_auth_file`: The path to a file which contains SMTP authentication credentials. The path can be either absolute or relative to the given rule. It should be YAML formatted and contain two fields, `user` and `password`. If this is not present, no authentication will be attempted.

`smtp_cert_file`: Connect the SMTP host using the given path to a TLS certificate file, default to `None`.

`smtp_key_file`: Connect the SMTP host using the given path to a TLS key file, default to `None`.

`email_reply_to`: This sets the Reply-To header in the email. By default, the from address is `ElastAlert@` and the domain will be set by the smtp server.

`from_addr`: This sets the From header in the email. By default, the from address is `ElastAlert@` and the domain will be set by the smtp server.

`cc`: This adds the CC emails to the list of recipients. By default, this is left empty.

single address example:

```
cc: "one@domain"
```

or

multiple address example:

```
cc:
  - "one@domain"
  - "two@domain"
```

`bcc`: This adds the BCC emails to the list of recipients but does not show up in the email message. By default, this is left empty.

single address example:

```
bcc: "one@domain"
```

or

multiple address example:

```
bcc:
  - "one@domain"
  - "two@domain"
```

`email_format`: If set to `'html'`, the email's MIME type will be set to HTML, and HTML content should correctly render. If you use this, you need to put your own HTML into `alert_text` and use `alert_text_type: alert_text_jinja` Or `alert_text_type: alert_text_only`.

`assets_dir`: images dir. default to `/tmp`.

`email_image_keys`: mapping between images keys.

`email_image_values`: mapping between images values

Example `assets_dir`, `email_image_keys`, `email_image_values`:

```
assets_dir: "/opt/elastalert/email_images"
email_image_keys: ["img1"]
email_image_values: ["my_logo.png"]
```

### 6.4.12 Exotel

Developers in India can use the Exotel alerter, which can send an alert to a mobile phone as an SMS from your Exo-Phone. The SMS will contain both the alert name and the specified message body.

The alerter requires the following option:

**exotel\_account\_sid:** The SID of your Exotel account.

**exotel\_auth\_token:** The auth token associated with your Exotel account.

Instructions for finding the SID and auth token associated with your account can be found [on the Exotel website](#).

**exotel\_to\_number:** The phone number to which you would like to send the alert.

**exotel\_from\_number:** The ExoPhone number from which the alert will be sent.

The alerter has one optional argument:

**exotel\_message\_body:** The contents of the SMS. If you don't specify this argument, only the rule name is sent.

Example usage:

```
alert:
  - "exotel"
exotel_account_sid: "Exotel Account SID"
exotel_auth_token: "Exotel Auth token"
exotel_to_number: "Exotel to number"
exotel_from_number: "Exotel from number"
```

### 6.4.13 Gitter

Gitter alerter will send a notification to a predefined Gitter channel. The body of the notification is formatted the same as with other alerters.

The alerter requires the following option:

**gitter\_webhook\_url:** The webhook URL that includes your auth data and the ID of the channel (room) you want to post to. Go to the Integration Settings of the channel <https://gitter.im/ORG/CHANNEL#integrations> , click 'CUSTOM' and copy the resulting URL.

Optional:

**gitter\_msg\_level:** By default the alert will be posted with the 'error' level. You can use 'info' if you want the messages to be black instead of red.

**gitter\_proxy:** By default ElastAlert 2 will not use a network proxy to send notifications to Gitter. Set this option using `hostname:port` if you need to use a proxy. only supports https.

Example usage:

```

alert:
  - "gitter"
gitter_webhook_url: "Your Gitter Webhook URL"
gitter_msg_level: "error"

```

### 6.4.14 GoogleChat

GoogleChat alerter will send a notification to a predefined GoogleChat channel. The body of the notification is formatted the same as with other alerters.

The alerter requires the following options:

`googlechat_webhook_url`: The webhook URL that includes the channel (room) you want to post to. Go to the Google Chat website <https://chat.google.com> and choose the channel in which you wish to receive the notifications. Select 'Configure Webhooks' to create a new webhook or to copy the URL from an existing one. You can use a list of URLs to send to multiple channels.

Optional:

`googlechat_format`: Formatting for the notification. Can be either 'card' or 'basic' (default).

`googlechat_header_title`: Sets the text for the card header title. (Only used if format=card)

`googlechat_header_subtitle`: Sets the text for the card header subtitle. (Only used if format=card)

`googlechat_header_image`: URL for the card header icon. (Only used if format=card)

`googlechat_footer_kibanalink`: URL to Kibana to include in the card footer. (Only used if format=card)

`googlechat_proxy`: By default ElastAlert 2 will not use a network proxy to send notifications to GoogleChat. Set this option using `hostname:port` if you need to use a proxy. only supports https.

### 6.4.15 Graylog GELF

GELF alerter will send a custom message to a Graylog GELF input (HTTP/TCP). Alert payload content you form with key-value pairs.

The alerter requires the following options:

`gelf_type`: Type of your Graylog GELF Input. How available 'http' or 'tcp'.

And in case of HTTP:

`gelf_endpoint`: Link to GELF HTTP Input as an example: 'http://example.com/gelf' (Only used if gelf\_type=http)

Or next if selected TCP:

`gelf_host`: Graylog server address where Input launched. (Only used if gelf\_type=tcp)

`gelf_port`: Port, specified for Input. (Only used if gelf\_type=tcp)

`gelf_payload`: Main message body. Working as key-value, where the key is your custom name and value - data from elasticsearch message. Name of alert will write to beginning of the message.

Example usage:

```

alert:
  - gelf
gelf_type: http
gelf_endpoint: http://example.com:12201/gelf

```

(continues on next page)

(continued from previous page)

```
gelf_payload:
  username: user
  src_ip: source_ip
```

Optional:

**gelf\_log\_level:** Standard syslog severity levels. By default set 5 (Notice)

**gelf\_http\_headers:** Additional headers. (Only used if **gelf\_type=http**)

**gelf\_ca\_cert:** Path to custom CA certificate.

**gelf\_http\_ignore\_ssl\_errors:** Ignore ssl error. (Only used if **gelf\_type=http**)

**gelf\_timeout:** Custom timeout.

### 6.4.16 Grafana OnCall

<https://grafana.com/docs/oncall/latest/integrations/elastalert/>

### 6.4.17 HTTP POST

This alert type will send results to a JSON endpoint using HTTP POST. The key names are configurable so this is compatible with almost any endpoint. By default, the JSON will contain all the items from the match, unless you specify **http\_post\_payload**, in which case it will only contain those items.

Required:

**http\_post\_url:** The URL to POST.

Optional:

**http\_post\_payload:** List of keys:values to use as the content of the POST. Example - **ip:clientip** will map the value from the **clientip** index of Elasticsearch to JSON key named **ip**. If not defined, all the Elasticsearch keys will be sent.

**http\_post\_static\_payload:** Key:value pairs of static parameters to be sent, along with the Elasticsearch results. Put your authentication or other information here.

**http\_post\_headers:** Key:value pairs of headers to be sent as part of the request.

**http\_post\_proxy:** URL of proxy, if required. only supports https.

**http\_post\_all\_values:** Boolean of whether or not to include every key value pair from the match in addition to those in **http\_post\_payload** and **http\_post\_static\_payload**. Defaults to True if **http\_post\_payload** is not specified, otherwise False.

**http\_post\_timeout:** The timeout value, in seconds, for making the post. The default is 10. If a timeout occurs, the alert will be retried next time elastalert cycles.

**http\_post\_ca\_certs:** Set this option to True or a path to a CA cert bundle or directory (eg: **/etc/ssl/certs/ca-certificates.crt**) to validate the SSL certificate.

**http\_post\_ignore\_ssl\_errors:** By default ElastAlert 2 will verify SSL certificate. Set this option to True if you want to ignore SSL errors.

Example usage:

```

alert: post
http_post_url: "http://example.com/api"
http_post_payload:
  ip: clientip
http_post_static_payload:
  apikey: abc123
http_post_headers:
  authorization: Basic 123dr3234

```

## 6.4.18 HTTP POST 2

This alert type will send results to a JSON endpoint using HTTP POST. The key names are configurable so this is compatible with almost any endpoint. By default, the JSON will contain all the items from the match, unless you specify `http_post_payload`, in which case it will only contain those items. This alert is a more flexible version of the HTTP Post alerter.

Required:

`http_post2_url`: The URL to POST.

Optional:

`http_post2_payload`: A JSON string or list of keys:values to use for the payload of the HTTP Post. You can use `{{ field }}` (Jinja2 template) in the key and the value to reference any field in the matched events (works for nested ES fields and nested payload keys). If not defined, all the Elasticsearch keys will be sent. Ex: `"description_{{ my_field }}"`: `"Type: {{ type }}"`  
`Subject: {{ title }}`". When field names use dot notation or reserved characters, `_data` can be used to access these fields. If `_data` conflicts with your top level data, use `jinja_root_name` to change its name.

`http_post2_raw_fields`: List of keys:values to use as the content of the POST. Example - `ip:clientip` will map the value from the `clientip` field of Elasticsearch to JSON key named `ip`. This field overwrite the keys with the same name in `http_post2_payload`.

`http_post2_headers`: A JSON string or list of keys:values to use for as headers of the HTTP Post. You can use `{{ field }}` (Jinja2 template) in the key and the value to reference any field in the matched events (works for nested fields). Ex: `"Authorization": "{{ user }}"`. Headers `"Content-Type": "application/json"` and `"Accept": "application/json; charset=utf-8"` are present by default, you can overwrite them if you think this is necessary. When field names use dot notation or reserved characters, `_data` can be used to access these fields. If `_data` conflicts with your top level data, use `jinja_root_name` to change its name.

`http_post2_proxy`: URL of proxy, if required. only supports https.

`http_post2_all_values`: Boolean of whether or not to include every key value pair from the match in addition to those in `http_post2_payload` and `http_post2_static_payload`. Defaults to True if `http_post2_payload` is not specified, otherwise False.

`http_post2_timeout`: The timeout value, in seconds, for making the post. The default is 10. If a timeout occurs, the alert will be retried next time elastalert cycles.

`http_post2_ca_certs`: Set this option to True or a path to a CA cert bundle or directory (eg: `/etc/ssl/certs/ca-certificates.crt`) to validate the SSL certificate.

`http_post2_ignore_ssl_errors`: By default ElastAlert 2 will verify SSL certificate. Set this option to True if you want to ignore SSL errors.

**Note:** Due to how values are rendered to JSON, the `http_post2_headers` and `http_post2_payload` fields require single quotes where quotes are required for Jinja templating. This only applies when using the YAML key:value pairs. Any

quotes can be used with the new JSON string format. See below for examples of how to properly use quotes as well as an example of the new JSON string formatting.

---

Incorrect usage with double quotes:

```
alert: post2
http_post2_url: "http://example.com/api"
http_post2_payload:
  # this will result in an error as " is escaped to \
  description: 'hello {{ _data["name"] }}'
  # this will result in an error as " is escaped to \
  state: '{{ ["low","medium","high","critical"][event.severity] }}'
http_post2_headers:
  authorization: Basic 123dr3234
  X-custom-type: '{{type}}'
```

Correct usage with single quotes:

```
alert: post2
http_post2_url: "http://example.com/api"
http_post2_payload:
  description: hello {{ _data['name'] }}
  state: '{{ ["low","medium","high","critical"][event.severity] }}'
http_post2_headers:
  authorization: Basic 123dr3234
  X-custom-type: '{{type}}'
```

Example usage:

```
alert: post2
http_post2_url: "http://example.com/api"
http_post2_payload:
  description: "An event came from IP {{clientip}}"
  username: "{{user.name}}"
http_post2_raw_fields:
  ip: clientip
http_post2_headers:
  authorization: Basic 123dr3234
  X-custom-type: {{type}}
```

Example usage with json string formatting:

```
alert: post2
jinja_root_name: _new_root
http_post2_url: "http://example.com/api"
http_post2_payload: |
{
  "description": "An event came from IP {{ _new_root["client.ip"] }}",
  "username": "{{ _new_root['username'] }}"
  {%- for k, v in some_field.items() -%}
  , "{{ k }}": "changed_{{ v }}"
  {%- endfor -%}
}
http_post2_raw_fields:
```

(continues on next page)

(continued from previous page)

```

ip: clientip
http_post2_headers: |
{
  "authorization": "Basic 123dr3234",
  "X-custom-{{key}}": "{{type}}"
}

```

### 6.4.19 IRIS

The Iris alerter can be used to create a new alert or case in [Iris IRP System](#). The alerter supports adding tags, IOCs, and context from the alert matches and rule data.

The alerter requires the following option:

**iris\_host:** Address of the Iris host. Exclude [https://](#) For example: `iris.example.com`.

**iris\_api\_token:** The API key of the user you created, which will be used to initiate alerts and cases on behalf of this user.

Optional:

**iris\_customer\_id:** This field represents the unique identifier of the customer for whom an incident/case will be created within the system. Configure and view the existing options in the section [Advanced -> Customers](#) of your IRIS instance. The default value is: 1

**iris\_ca\_cert:** Path to custom CA certificate.

**iris\_ignore\_ssl\_errors:** Ignore ssl error. The default value is: False.

**iris\_description:** Description of the alert or case.

**iris\_overwrite\_timestamp:** Should the timestamp be overridden when creating an alert. By default, the alert's creation time will be the trigger time. If you want to use the event's timestamp as the ticket creation time, set this value to True. Default value is False.

**iris\_type:** The type of object being created. It can be either `alert` or `case`. The default value is `alert`.

**iris\_case\_template\_id:** Case template ID, if you want to apply a pre-prepared template.

**iris\_alert\_note:** Note for the alert.

**iris\_alert\_tags:** List of tags.

**iris\_alert\_status\_id:** The alert status of the alert, default value is 2. This parameter requires an integer input.

Possible values:

- 1 - Unspecified
- 2 - New
- 3 - Assigned
- 4 - In progress
- 5 - Pending
- 6 - Closed
- 7 - Merged.

`iris_alert_source_link`: Your custom link, if needed.

`iris_alert_severity_id`: The severity level of the alert, default value is 1. This parameter requires an integer input.

Possible values:

- 1 - Unspecified
- 2 - Informational
- 3 - Low
- 4 - Medium
- 5 - High
- 6 - Critical.

`iris_alert_context`: Include information from the match into the alert context. Working as key-value, where the key is your custom name and value - data from elasticsearch message.

`iris_iocs`: Description of the IOC to be added.

Example usage `iris_iocs`:

```
iris_iocs:
- ioc_value: ip
  ioc_description: Suspicious IP address
  ioc_tlp_id: 2
  ioc_type_id: 76
  ioc_tags: ipv4, ip, suspicious
- ioc_value: username
  ioc_description: Suspicious username
  ioc_tlp_id: 1
  ioc_type_id: 3
  ioc_tags: username
```

A few words about `ioc_tlp_id` and `ioc_type_id`. `ioc_tlp_id` can be of three types: 1 - red, 2 - amber, 3 - green. There are numerous values for `ioc_type_id`, and you can also add your custom ones. To find the ID for the type you are interested in, refer to your Iris instance's API at '<https://example.com/manage/ioc-types/list>'.

You can find complete examples of rules in the repository under the 'examples' folder.

## 6.4.20 Jira

The Jira alerter will open a ticket on Jira whenever an alert is triggered. You must have a service account for ElastAlert 2 to connect with. The credentials of the service account are loaded from a separate file. Credentials can either be username and password or the Personal Access Token. The ticket number will be written to the alert pipeline, and if it is followed by an email alerter, a link will be included in the email.

This alert requires four additional options:

`jira_server`: The hostname of the Jira server.

`jira_project`: The project to open the ticket under.

`jira_issuetype`: The type of issue that the ticket will be filed as. Note that this is case sensitive.

`jira_account_file`: The path to the file which contains Jira account credentials.

For an example Jira account file, see `examples/rules/jira_acct.yaml`. The account file is a YAML formatted file.

When using user/password authentication, or when using Jira Cloud the Jira account file must contain two fields:

**user:** The username to authenticate with Jira.

**password:** The password to authenticate with Jira. Jira cloud users must specify the Jira Cloud API token for this value.

When using a Personal Access Token, such as when using a locally hosted Jira installation, the Jira account file must contain a single field:

**apikey:** The Personal Access Token for authenticating with Jira.

Optional:

**jira\_parent:** Specify an existing ticket that will be used as a parent to create a new subtask in it

**For example, if you have this issue hierarchy:**

Epic Story, Task, Bug Subtask

**Then:**

As a parent issue, an epic can have stories, tasks, and bugs as subtask (child issues). As a parent issues, task, stories and bugs can have subtasks as subtask (child issues). A subtask can't have any subtask (child issues).

Example usage:

```
jira_server: "https://example.atlassian.net/"
jira_project: "XXX"
jira_assignee: user@example.com
jira_issuetype: "Sub-task"
jira_parent: "XXX-3164"
```

**jira\_assignee:** Assigns an issue to a user.

**jira\_component:** The name of the component or components to set the ticket to. This can be a single string or a list of strings. This is provided for backwards compatibility and will eventually be deprecated. It is preferable to use the plural `jira_components` instead.

**jira\_components:** The name of the component or components to set the ticket to. This can be a single string or a list of strings.

**jira\_description:** Similar to `alert_text`, this text is prepended to the Jira description.

**jira\_label:** The label or labels to add to the Jira ticket. This can be a single string or a list of strings. This is provided for backwards compatibility and will eventually be deprecated. It is preferable to use the plural `jira_labels` instead.

**jira\_labels:** The label or labels to add to the Jira ticket. This can be a single string or a list of strings.

**jira\_priority:** The index of the priority to set the issue to. In the Jira dropdown for priorities, 0 would represent the first priority, 1 the 2nd, etc.

**jira\_watchers:** A list of user names to add as watchers on a Jira ticket. This can be a single string or a list of strings.

**jira\_bump\_tickets:** If true, ElastAlert 2 search for existing tickets newer than `jira_max_age` and comment on the ticket with information about the alert instead of opening another ticket. ElastAlert 2 finds the existing ticket by searching by summary. If the summary has changed or contains special characters, it may fail to find the ticket. If you are using a custom `alert_subject`, the two summaries must be exact matches, except by setting `jira_ignore_in_title`, you can ignore the value of a field when searching. For example, if the custom subject is "foo occurred at bar", and "foo" is

the value field X in the match, you can set `jira_ignore_in_title` to “X” and it will only bump tickets with “bar” in the subject. Defaults to false.

`jira_ignore_in_title`: ElastAlert 2 will attempt to remove the value for this field from the Jira subject when searching for tickets to bump. See `jira_bump_tickets` description above for an example.

`jira_max_age`: If `jira_bump_tickets` is true, the maximum age of a ticket, in days, such that ElastAlert 2 will comment on the ticket instead of opening a new one. Default is 30 days.

`jira_bump_not_in_statuses`: If `jira_bump_tickets` is true, a list of statuses the ticket must **not** be in for ElastAlert 2 to comment on the ticket instead of opening a new one. For example, to prevent comments being added to resolved or closed tickets, set this to ‘Resolved’ and ‘Closed’. This option should not be set if the `jira_bump_in_statuses` option is set.

Example usage:

```
jira_bump_not_in_statuses:
- Resolved
- Closed
```

`jira_bump_in_statuses`: If `jira_bump_tickets` is true, a list of statuses the ticket *must be in* for ElastAlert 2 to comment on the ticket instead of opening a new one. For example, to only comment on ‘Open’ tickets – and thus not ‘In Progress’, ‘Analyzing’, ‘Resolved’, etc. tickets – set this to ‘Open’. This option should not be set if the `jira_bump_not_in_statuses` option is set.

Example usage:

```
jira_bump_in_statuses:
- Open
```

`jira_bump_only`: Only update if a ticket is found to bump. This skips ticket creation for rules where you only want to affect existing tickets.

Example usage:

```
jira_bump_only: true
```

`jira_transition_to`: If `jira_bump_tickets` is true, Transition this ticket to the given Status when bumping. Must match the text of your Jira implementation’s Status field.

Example usage:

```
jira_transition_to: 'Fixed'
```

`jira_bump_after_inactivity`: If this is set, ElastAlert 2 will only comment on tickets that have been inactive for at least this many days. It only applies if `jira_bump_tickets` is true. Default is 0 days.

Arbitrary Jira fields:

ElastAlert 2 supports setting any arbitrary Jira field that your Jira issue supports. For example, if you had a custom field, called “Affected User”, you can set it by providing that field name in `snake_case` prefixed with `jira_`. These fields can contain primitive strings or arrays of strings. Note that when you create a custom field in your Jira server, internally, the field is represented as `customfield_1111`. In ElastAlert 2, you may refer to either the public facing name OR the internal representation.

In addition, if you would like to use a field in the alert as the value for a custom Jira field, use the field name plus a `#` symbol in front. For example, if you wanted to set a custom Jira field called “user” to the value of the field “username” from the match, you would use the following.

Example:

```
jira_user: "#username"
```

Example usage:

```
jira_arbitrary_singular_field: My Name
jira_arbitrary_multivalue_field:
  - Name 1
  - Name 2
jira_customfield_12345: My Custom Value
jira_customfield_9999:
  - My Custom Value 1
  - My Custom Value 2
```

### 6.4.21 Lark

Lark alerter will send notification to a predefined bot in Lark application. The body of the notification is formatted the same as with other alerters.

Required:

`lark_bot_id`: Lark bot id.

Optional:

`lark_msgtype`: Lark msgtype, currently only `text` supported.

Example usage:

```
alert:
  - "lark"
lark_bot_id: "your lark bot id"
lark_msgtype: "text"
```

### 6.4.22 Line Notify

Line Notify will send notification to a Line application. The body of the notification is formatted the same as with other alerters.

Required:

`linenotify_access_token`: The access token that you got from <https://notify-bot.line.me/my/>

Example usage:

```
alert:
  - "linenotify"
linenotify_access_token: "Your linenotify access token"
```

### 6.4.23 Mattermost

Mattermost alerter will send a notification to a predefined Mattermost channel. The body of the notification is formatted the same as with other alerters.

The alerter requires the following option:

**mattermost\_webhook\_url:** The webhook URL. Follow the instructions on <https://developers.mattermost.com/integrate/webhooks/incoming/> to create an incoming webhook on your Mattermost installation.

Optional:

**mattermost\_proxy:** By default ElastAlert 2 will not use a network proxy to send notifications to Mattermost. Set this option using `hostname:port` if you need to use a proxy. only supports https.

**mattermost\_ignore\_ssl\_errors:** By default ElastAlert 2 will verify SSL certificate. Set this option to `True` if you want to ignore SSL errors.

**mattermost\_username\_override:** By default Mattermost will use your username when posting to the channel. Use this option to change it (free text).

**mattermost\_channel\_override:** Incoming webhooks have a default channel, but it can be overridden. A public channel can be specified `"#other-channel"`, and a Direct Message with `"@username"`.

**mattermost\_emoji\_override:** By default ElastAlert 2 will use the `:ghost:` emoji when posting to the channel. You can use a different emoji per ElastAlert 2 rule. Any Apple emoji can be used, see <http://emojipedia.org/apple/>. If **mattermost\_icon\_url\_override** parameter is provided, emoji is ignored.

**mattermost\_icon\_url\_override:** By default ElastAlert 2 will use the `:ghost:` emoji when posting to the channel. You can provide `icon_url` to use custom image. Provide absolute address of the picture.

**mattermost\_msg\_pretext:** You can set the message attachment pretext using this option.

**mattermost\_msg\_color:** By default the alert will be posted with the 'danger' color. You can also use 'good', 'warning', or hex color code.

**mattermost\_msg\_fields:** You can add fields to your Mattermost alerts using this option. You can specify the title using *title* and the text value using *value*. Additionally you can specify whether this field should be a *short* field using *short: true*. If you set *args* and *value* is a formattable string, ElastAlert 2 will format the incident key based on the provided array of fields from the rule or match. See <https://developers.mattermost.com/integrate/reference/message-attachments/#fields> for more information.

Example **mattermost\_msg\_fields**:

```
mattermost_msg_fields:
- title: Stack
  value: "{0} {1}" # interpolate fields mentioned in args
  short: false
  args: ["type", "msg.status_code"] # fields from doc
- title: Name
  value: static field
  short: false
```

**mattermost\_title:** Sets a title for the message, this shows up as a blue text at the start of the message. Defaults to "".

**mattermost\_title\_link:** You can add a link in your Mattermost notification by setting this to a valid URL. Requires **mattermost\_title** to be set. Defaults to "".

**mattermost\_footer:** Add a static footer text for alert. Defaults to "".

**mattermost\_footer\_icon:** A Public Url for a footer icon. Defaults to "".

`mattermost_image_url`: An optional URL to an image file (GIF, JPEG, PNG, BMP, or SVG). Defaults to "".

`mattermost_thumb_url`: An optional URL to an image file (GIF, JPEG, PNG, BMP, or SVG) that is displayed as thumbnail. Defaults to "".

`mattermost_author_name`: An optional name used to identify the author. Defaults to "".

`mattermost_author_link`: An optional URL used to hyperlink the `author_name`. Defaults to "".

`mattermost_author_icon`: An optional URL used to display a 16x16 pixel icon beside the `author_name`. Defaults to "".

`mattermost_attach_kibana_discover_url`: Enables the attachment of the `kibana_discover_url` to the mattermost notification. The config `generate_kibana_discover_url` must also be `True` in order to generate the url. Defaults to `False`.

`mattermost_kibana_discover_color`: The color of the Kibana Discover url attachment. Defaults to `#ec4b98`.

`mattermost_kibana_discover_title`: The title of the Kibana Discover url attachment. Defaults to `Discover in Kibana`.

`mattermost_attach_opensearch_discover_url`: Enables the attachment of the `opensearch_discover_url` to the mattermost notification. The config `generate_opensearch_discover_url` must also be `True` in order to generate the url. Defaults to `False`.

`mattermost_opensearch_discover_color`: The color of the Opensearch Discover url attachment. Defaults to `#ec4b98`.

`mattermost_opensearch_discover_title`: The title of the Opensearch Discover url attachment. Defaults to `Discover in opensearch`.

Example      `mattermost_attach_kibana_discover_url`,      `mattermost_kibana_discover_color`,      `mattermost_kibana_discover_title`:

```
# (Required)
generate_kibana_discover_url: True
kibana_discover_app_url: "http://localhost:5601/app/discover#/"
kibana_discover_index_pattern_id: "4babf380-c3b1-11eb-b616-1b59c2feec54"
kibana_discover_version: "7.15"

# (Optional)
kibana_discover_from_timedelta:
  minutes: 10
kibana_discover_to_timedelta:
  minutes: 10

# (Required)
mattermost_attach_kibana_discover_url: True

# (Optional)
mattermost_kibana_discover_color: "#ec4b98"
mattermost_kibana_discover_title: "Discover in Kibana"
```

Example      `mattermost_attach_opensearch_discover_url`,      `mattermost_kibana_discover_color`,      `mattermost_kibana_discover_title`:

```
# (Required)
generate_opensearch_discover_url: True
opensearch_discover_app_url: "http://localhost:5601/app/discover#/"
```

(continues on next page)

(continued from previous page)

```

opensearch_discover_index_pattern_id: "4babf380-c3b1-11eb-b616-1b59c2feec54"
opensearch_discover_version: "2.11"

# (Optional)
opensearch_discover_from_timedelta:
  minutes: 10
opensearch_discover_to_timedelta:
  minutes: 10

# (Required)
mattermost_attach_opensearch_discover_url: True

# (Optional)
mattermost_opensearch_discover_color: "#ec4b98"
mattermost_opensearch_discover_title: "Discover in opensearch"

```

## 6.4.24 Microsoft Teams

Microsoft Teams alerter will send a notification to a predefined Microsoft Teams channel.

The alerter requires the following options:

**ms\_teams\_webhook\_url:** The webhook URL that includes your auth data and the ID of the channel you want to post to. Go to the Connectors menu in your channel and configure an Incoming Webhook, then copy the resulting URL. You can use a list of URLs to send to multiple channels.

Optional:

**ms\_teams\_alert\_summary:** MS Teams use this value for notification title, defaults to [Alert Subject](#). You can set this value with arbitrary text if you don't want to use the default.

**ms\_teams\_theme\_color:** By default the alert will be posted without any color line. To add color, set this attribute to a HTML color value e.g. `#ff0000` for red.

**ms\_teams\_proxy:** By default ElastAlert 2 will not use a network proxy to send notifications to MS Teams. Set this option using `hostname:port` if you need to use a proxy. only supports https.

**ms\_teams\_alert\_fixed\_width:** By default this is `False` and the notification will be sent to MS Teams as-is. Teams supports a partial Markdown implementation, which means asterisk, underscore and other characters may be interpreted as Markdown. Currently, Teams does not fully implement code blocks. Setting this attribute to `True` will enable line by line code blocks. It is recommended to enable this to get clearer notifications in Teams.

**ms\_teams\_alert\_facts:** You can add additional facts to your MS Teams alerts using this field. Specify the title using *name* and a value for the field or arbitrary text using *value*.

Example `ms_teams_alert_facts`:

```

ms_teams_alert_facts:
- name: Host
  value: monitor.host
- name: Status
  value: monitor.status
- name: What to do
  value: Page your boss

```

`ms_teams_attach_kibana_discover_url`: Enables the attachment of the `kibana_discover_url` to the MS Teams notification. The config `generate_kibana_discover_url` must also be `True` in order to generate the url. Defaults to `False`.

`ms_teams_kibana_discover_title`: The title of the Kibana Discover url attachment. Defaults to `Discover in Kibana`.

`ms_teams_attach_opensearch_discover_url`: Enables the attachment of the `opensearch_discover_url` to the MS Teams notification. The config `generate_opensearch_discover_url` must also be `True` in order to generate the url. Defaults to `False`.

`ms_teams_opensearch_discover_title`: The title of the Opensearch Discover url attachment. Defaults to `Discover in opensearch`.

Example `ms_teams_attach_kibana_discover_url`, `ms_teams_kibana_discover_title`:

```
# (Required)
generate_kibana_discover_url: True
kibana_discover_app_url: "http://localhost:5601/app/discover#/"
kibana_discover_index_pattern_id: "4babf380-c3b1-11eb-b616-1b59c2feec54"
kibana_discover_version: "7.15"

# (Optional)
kibana_discover_from_timedelta:
  minutes: 10
kibana_discover_to_timedelta:
  minutes: 10

# (Required)
ms_teams_attach_kibana_discover_url: True

# (Optional)
ms_teams_kibana_discover_title: "Discover in Kibana"
```

Example `ms_teams_attach_opensearch_discover_url`, `ms_teams_opensearch_discover_title`:

```
# (Required)
generate_opensearch_discover_url: True
opensearch_discover_app_url: "http://localhost:5601/app/discover#/"
opensearch_discover_index_pattern_id: "4babf380-c3b1-11eb-b616-1b59c2feec54"
opensearch_discover_version: "7.15"

# (Optional)
opensearch_discover_from_timedelta:
  minutes: 10
opensearch_discover_to_timedelta:
  minutes: 10

# (Required)
ms_teams_attach_opensearch_discover_url: True

# (Optional)
ms_teams_opensearch_discover_title: "Discover in opensearch"
```

`ms_teams_ca_certs`: Set this option to `True` or a path to a CA cert bundle or directory (eg: `/etc/ssl/certs/ca-certificates.crt`) to validate the SSL certificate.

`ms_teams_ignore_ssl_errors`: By default ElastAlert 2 will verify SSL certificate. Set this option to `True` if you want to ignore SSL errors.

Example usage:

```
alert:
  - "ms_teams"
ms_teams_theme_color: "#6600ff"
ms_teams_webhook_url: "MS Teams Webhook URL"
```

## 6.4.25 OpsGenie

OpsGenie alerter will create an alert which can be used to notify Operations people of issues or log information. An OpsGenie API integration must be created in order to acquire the necessary `opsgenie_key` rule variable. Currently the OpsGenieAlerter only creates an alert, however it could be extended to update or close existing alerts.

It is necessary for the user to create an OpsGenie Rest HTTPS API [integration page](#) in order to create alerts.

The OpsGenie alert requires one option:

`opsgenie_key`: The randomly generated API Integration key created by OpsGenie.

Optional:

`opsgenie_account`: The OpsGenie account to integrate with.

`opsgenie_addr`: The OpsGenie URL to connect against, default is `https://api.opsgenie.com/v2/alerts`. If using the EU instance of Opsgenie, the URL needs to be `https://api.eu.opsgenie.com/v2/alerts` for requests to be successful.

`opsgenie_recipients`: A list OpsGenie recipients who will be notified by the alert.

`opsgenie_recipients_args`: Map of arguments used to format `opsgenie_recipients`.

`opsgenie_default_receipients`: List of default recipients to notify when the formatting of `opsgenie_recipients` is unsuccessful.

`opsgenie_teams`: A list of OpsGenie teams to notify (useful for schedules with escalation).

`opsgenie_teams_args`: Map of arguments used to format `opsgenie_teams` (useful for assigning the alerts to teams based on some data).

`opsgenie_default_teams`: List of default teams to notify when the formatting of `opsgenie_teams` is unsuccessful.

`opsgenie_tags`: A list of tags for this alert.

`opsgenie_message`: Set the OpsGenie message to something other than the rule name. The message can be formatted with fields from the first match e.g. "Error occurred for {app\_name} at {timestamp}."

`opsgenie_description`: Set the OpsGenie description to something other than the rule body. The message can be formatted with fields from the first match e.g. "Error occurred for {app\_name} at {timestamp}."

`opsgenie_alias`: Set the OpsGenie alias. The alias can be formatted with fields from the first match e.g. "{app\_name} error".

`opsgenie_subject`: A string used to create the title of the OpsGenie alert. Can use Python string formatting.

`opsgenie_subject_args`: A list of fields to use to format `opsgenie_subject` if it contains formatters.

`opsgenie_priority`: Set the OpsGenie priority level. Possible values are P1, P2, P3, P4, P5. Can be formatted with fields from the first match e.g. "P{level}"

`opsgenie_details`: Map of custom key/value pairs to include in the alert's details. The value can sourced from either fields in the first match, environment variables, or a constant value.

`opsgenie_proxy`: By default ElastAlert 2 will not use a network proxy to send notifications to OpsGenie. Set this option using `hostname:port` if you need to use a proxy. only supports https.

`opsgenie_source`: Set the OpsGenie source, default is *ElastAlert*. Can be formatted with fields from the first match e.g “{source} {region}”

`opsgenie_entity`: Set the OpsGenie entity. Can be formatted with fields from the first match e.g “{host\_name}”

Example usage:

```
opsgenie_details:
  Author: 'Bob Smith'           # constant value
  Environment: '$VAR'           # environment variable
  Message: { field: message }   # field in the first match
```

Example `opsgenie_details` with `kibana_discover_url`:

```
# (Required)
generate_kibana_discover_url: True
kibana_discover_app_url: "http://localhost:5601/app/discover#/"
kibana_discover_index_pattern_id: "4babf380-c3b1-11eb-b616-1b59c2feec54"
kibana_discover_version: "7.15"

# (Optional)
kibana_discover_from_timedelta:
  minutes: 10
kibana_discover_to_timedelta:
  minutes: 10

# (Required)
opsgenie_details:
  Kibana Url: { field: kibana_discover_url }
  Message: { field: message }
  Testing: 'yes'
```

## 6.4.26 PagerDuty

PagerDuty alerter will trigger an incident to a predefined PagerDuty service. The body of the notification is formatted the same as with other alerters.

The alerter requires the following option:

`pagerduty_service_key`: Integration Key generated after creating a service with the ‘Use our API directly’ option at Integration Settings

`pagerduty_client_name`: The name of the monitoring client that is triggering this event.

`pagerduty_event_type`: Any of the following: *trigger*, *resolve*, or *acknowledge*. (Optional, defaults to *trigger*)

Optional:

`alert_subject`: If set, this will be used as the Incident description within PagerDuty. If not set, ElastAlert 2 will default to using the rule name of the alert for the incident.

`alert_subject_args`: If set, and `alert_subject` is a formattable string, ElastAlert 2 will format the incident key based on the provided array of fields from the rule or match.

`pagerduty_incident_key`: If not set PagerDuty will trigger a new incident for each alert sent. If set to a unique string per rule PagerDuty will identify the incident that this event should be applied. If there's no open (i.e. unresolved) incident with this key, a new one will be created. If there's already an open incident with a matching key, this event will be appended to that incident's log.

`pagerduty_incident_key_args`: If set, and `pagerduty_incident_key` is a formattable string, ElastAlert 2 will format the incident key based on the provided array of fields from the rule or match.

`pagerduty_proxy`: By default ElastAlert 2 will not use a network proxy to send notifications to PagerDuty. Set this option using `hostname:port` if you need to use a proxy. only supports https.

`pagerduty_ca_certs`: Set this option to True or a path to a CA cert bundle or directory (eg: `/etc/ssl/certs/ca-certificates.crt`) to validate the SSL certificate.

`pagerduty_ignore_ssl_errors`: By default ElastAlert 2 will verify SSL certificate. Set this option to True if you want to ignore SSL errors.

#### V2 API Options (Optional):

These options are specific to the PagerDuty V2 API

See <https://developer.pagerduty.com/api-reference/b3A6Mjc0ODI2Nw-send-an-event-to-pager-duty>

`pagerduty_api_version`: Defaults to `v1`. Set to `v2` to enable the PagerDuty V2 Event API.

`pagerduty_v2_payload_class`: Sets the class of the payload. (the event type in PagerDuty)

`pagerduty_v2_payload_class_args`: If set, and `pagerduty_v2_payload_class` is a formattable string, ElastAlert 2 will format the class based on the provided array of fields from the rule or match.

`pagerduty_v2_payload_component`: Sets the component of the payload. (what program/interface/etc the event came from)

`pagerduty_v2_payload_component_args`: If set, and `pagerduty_v2_payload_component` is a formattable string, ElastAlert 2 will format the component based on the provided array of fields from the rule or match.

`pagerduty_v2_payload_group`: Sets the logical grouping (e.g. app-stack)

`pagerduty_v2_payload_group_args`: If set, and `pagerduty_v2_payload_group` is a formattable string, ElastAlert 2 will format the group based on the provided array of fields from the rule or match.

`pagerduty_v2_payload_severity`: Sets the severity of the page. (defaults to *critical*, valid options: *critical*, *error*, *warning*, *info*)

`pagerduty_v2_payload_source`: Sets the source of the event, preferably the hostname or fqdn.

`pagerduty_v2_payload_source_args`: If set, and `pagerduty_v2_payload_source` is a formattable string, ElastAlert 2 will format the source based on the provided array of fields from the rule or match.

`pagerduty_v2_payload_custom_details`: List of keys:values to use as the content of the custom\_details payload. Example - `ip:clientip` will map the value from the clientip index of Elasticsearch to JSON key named `ip`.

`pagerduty_v2_payload_include_all_info`: If True, this will include the entire Elasticsearch document as a custom detail field called "information" in the PagerDuty alert.

### 6.4.27 PagerTree

PagerTree alerter will trigger an incident to a predefined PagerTree integration url.

The alerter requires the following options:

`pagertree_integration_url`: URL generated by PagerTree for the integration.

`pagertree_proxy`: By default ElastAlert 2 will not use a network proxy to send notifications to PagerTree. Set this option using `hostname:port` if you need to use a proxy. only supports https.

Example usage:

```
alert:
  - "pagertree"
pagertree_integration_url: "PagerTree Integration URL"
```

### 6.4.28 Rocket.Chat

Rocket.Chat alerter will send a notification to a predefined channel. The body of the notification is formatted the same as with other alerters. <https://developer.rocket.chat/api/rest-api/methods/chat/postmessage>

The alerter requires the following option:

`rocket_chat_webhook_url`: The webhook URL that includes your auth data and the ID of the channel (room) you want to post to. You can use a list of URLs to send to multiple channels.

Optional:

`rocket_chat_username_override`: By default Rocket.Chat will use username defined in Integration when posting to the channel. Use this option to change it (free text).

`rocket_chat_channel_override`: Incoming webhooks have a default channel, but it can be overridden. A public channel can be specified “#other-channel”, and a Direct Message with “@username”.

`rocket_chat_emoji_override`: By default ElastAlert 2 will use the :ghost: emoji when posting to the channel. You can use a different emoji per ElastAlert 2 rule. Any Apple emoji can be used, see <http://emojipedia.org/apple/> .

`rocket_chat_msg_color`: By default the alert will be posted with the ‘danger’ color. You can also use ‘good’ or ‘warning’ colors.

`rocket_chat_text_string`: Notification message you want to add.

`rocket_chat_proxy`: By default ElastAlert 2 will not use a network proxy to send notifications to Rocket.Chat. Set this option using `hostname:port` if you need to use a proxy. only supports https.

`rocket_chat_ca_certs`: Set this option to True or a path to a CA cert bundle or directory (eg: `/etc/ssl/certs/ca-certificates.crt`) to validate the SSL certificate.

`rocket_chat_ignore_ssl_errors`: By default ElastAlert 2 will verify SSL certificate. Set this option to True if you want to ignore SSL errors.

`rocket_chat_timeout`: You can specify a timeout value, in seconds, for making communicating with Rocket.Chat. The default is 10. If a timeout occurs, the alert will be retried next time ElastAlert 2 cycles.

`rocket_chat_attach_kibana_discover_url`: Enables the attachment of the `kibana_discover_url` to the Rocket.Chat notification. The config `generate_kibana_discover_url` must also be True in order to generate the url. Defaults to False.

`rocket_chat_kibana_discover_color`: The color of the Kibana Discover url attachment. Defaults to #ec4b98.

`rocket_chat_kibana_discover_title`: The title of the Kibana Discover url attachment. Defaults to Discover in Kibana.

`rocket_chat_attach_opensearch_discover_url`: Enables the attachment of the `opensearch_discover_url` to the Rocket.Chat notification. The config `generate_opensearch_discover_url` must also be True in order to generate the url. Defaults to False.

`rocket_chat_opensearch_discover_color`: The color of the Opensearch Discover url attachment. Defaults to #ec4b98.

`rocket_chat_opensearch_discover_title`: The title of the Opensearch Discover url attachment. Defaults to Discover in opensearch.

Example                      `rocket_chat_attach_kibana_discover_url`,                      `rocket_chat_kibana_discover_color`,  
`rocket_chat_kibana_discover_title`:

```
# (Required)
generate_kibana_discover_url: True
kibana_discover_app_url: "http://localhost:5601/app/discover#/"
kibana_discover_index_pattern_id: "4babf380-c3b1-11eb-b616-1b59c2feec54"
kibana_discover_version: "7.15"

# (Optional)
kibana_discover_from_timedelta:
  minutes: 10
kibana_discover_to_timedelta:
  minutes: 10

# (Required)
rocket_chat_attach_kibana_discover_url: True

# (Optional)
rocket_chat_kibana_discover_color: "#ec4b98"
rocket_chat_kibana_discover_title: "Discover in Kibana"
```

Example                      `rocket_chat_attach_opensearch_discover_url`,                      `rocket_chat_opensearch_discover_color`,  
`rocket_chat_opensearch_discover_title`:

```
# (Required)
generate_opensearch_discover_url: True
opensearch_discover_app_url: "http://localhost:5601/app/discover#/"
opensearch_discover_index_pattern_id: "4babf380-c3b1-11eb-b616-1b59c2feec54"
opensearch_discover_version: "2.11"

# (Optional)
opensearch_discover_from_timedelta:
  minutes: 10
opensearch_discover_to_timedelta:
  minutes: 10

# (Required)
rocket_chat_attach_opensearch_discover_url: True

# (Optional)
rocket_chat_opensearch_discover_color: "#ec4b98"
rocket_chat_opensearch_discover_title: "Discover in opensearch"
```

`rocket_chat_alert_fields`: You can add additional fields to your Rocket.Chat alerts using this field. Specify the title using *title* and a value for the field using *value*. Additionally you can specify whether or not this field should be a *short* field using *short*: *true*.

Example `rocket_chat_alert_fields`:

```
rocket_chat_alert_fields:
- title: Host
  value: monitor.host
  short: true
- title: Status
  value: monitor.status
  short: true
- title: Zone
  value: beat.name
  short: true
```

### 6.4.29 Squadcast

Alerts can be sent to Squadcast using the *http post* method described above and Squadcast will process it and send Phone, SMS, Email and Push notifications to the relevant person(s) and let them take actions.

Configuration variables in rules YAML file:

```
alert: post
http_post_url: <ElastAlert 2 Webhook URL copied from Squadcast dashboard>
http_post_static_payload:
  Title: <Incident Title>
http_post_all_values: true
```

For more details, you can refer the [Squadcast documentation](#).

### 6.4.30 ServiceNow

The ServiceNow alerter will create a new Incident in ServiceNow. The body of the notification is formatted the same as with other alerters.

The alerter requires the following options:

`servicenow_rest_url`: The ServiceNow RestApi url, this will look like [TableAPI](#).

`username`: The ServiceNow Username to access the api.

`password`: The ServiceNow password to access the api.

`short_description`: The ServiceNow password to access the api.

`comments`: Comments to be attached to the incident, this is the equivalent of work notes.

`assignment_group`: The group to assign the incident to.

`category`: The category to attach the incident to, use an existing category.

`subcategory`: The subcategory to attach the incident to, use an existing subcategory.

`cmdb_ci`: The configuration item to attach the incident to.

`caller_id`: The caller id (email address) of the user that created the incident ([elastalert@somewhere.com](mailto:elastalert@somewhere.com)).

Optional:

**servicenow\_proxy:** By default ElastAlert 2 will not use a network proxy to send notifications to ServiceNow. Set this option using `hostname:port` if you need to use a proxy. only supports https.

**servicenow\_impact:** An integer 1, 2, or 3 representing high, medium, and low respectively. This measures the effect of an incident on business processes.

**servicenow\_urgency:** An integer 1, 2, or 3 representing high, medium, and low respectively. This measures how long this incident can be delayed until there is a significant business impact.

Example usage:

```
alert:
  - "servicenow"
servicenow_rest_url: "servicenow rest url"
username: "user"
password: "password"
short_description: "xxxxxxx"
comments: "xxxxxxx"
assignment_group: "xxxxxxx"
category: "xxxxxxx"
subcategory: "xxxxxxx"
cmdb_ci: "xxxxxxx"
caller_id: "xxxxxxx"
servicenow_impact: 1
servicenow_urgenc: 3
```

### 6.4.31 Slack

Slack alerter will send a notification to a predefined Slack channel. The body of the notification is formatted the same as with other alerters.

The alerter requires the following option:

**slack\_webhook\_url:** The webhook URL that includes your auth data and the ID of the channel (room) you want to post to. Go to the Incoming Webhooks section in your Slack account <https://XXXXXX.slack.com/services/new/incoming-webhook>, choose the channel, click ‘Add Incoming Webhooks Integration’ and copy the resulting URL. You can use a list of URLs to send to multiple channels.

Optional:

**slack\_username\_override:** By default Slack will use your username when posting to the channel. Use this option to change it (free text).

**slack\_channel\_override:** Incoming webhooks have a default channel, but it can be overridden. A public channel can be specified “#other-channel”, and a Direct Message with “@username”.

**slack\_emoji\_override:** By default ElastAlert 2 will use the `:ghost:` emoji when posting to the channel. You can use a different emoji per ElastAlert 2 rule. Any Apple emoji can be used, see <http://emojipedia.org/apple/>. If `slack_icon_url_override` parameter is provided, emoji is ignored.

**slack\_icon\_url\_override:** By default ElastAlert 2 will use the `:ghost:` emoji when posting to the channel. You can provide `icon_url` to use custom image. Provide absolute address of the picture.

**slack\_msg\_color:** By default the alert will be posted with the ‘danger’ color. You can also use ‘good’ or ‘warning’ colors.

**slack\_parse\_override:** By default the notification message is escaped ‘none’. You can also use ‘full’.

`slack_text_string`: Notification message you want to add.

`slack_proxy`: By default ElastAlert 2 will not use a network proxy to send notifications to Slack. Set this option using `hostname:port` if you need to use a proxy. only supports https.

`slack_alert_fields`: You can add additional fields to your slack alerts using this field. Specify the title using *title* and a value for the field using *value*. Additionally you can specify whether or not this field should be a *short* field using *short*: *true*.

Example `slack_alert_fields`:

```
slack_alert_fields:
- title: Host
  value: monitor.host
  short: true
- title: Status
  value: monitor.status
  short: true
- title: Zone
  value: beat.name
  short: true
```

`slack_ignore_ssl_errors`: By default ElastAlert 2 will verify SSL certificate. Set this option to `True` if you want to ignore SSL errors.

`slack_title`: Sets a title for the message, this shows up as a blue text at the start of the message

`slack_title_link`: You can add a link in your Slack notification by setting this to a valid URL. Requires `slack_title` to be set.

`slack_timeout`: You can specify a timeout value, in seconds, for making communicating with Slack. The default is 10. If a timeout occurs, the alert will be retried next time ElastAlert 2 cycles.

`slack_attach_kibana_discover_url`: Enables the attachment of the `kibana_discover_url` to the slack notification. The config `generate_kibana_discover_url` must also be `True` in order to generate the url. Defaults to `False`.

`slack_kibana_discover_color`: The color of the Kibana Discover url attachment. Defaults to `#ec4b98`.

`slack_kibana_discover_title`: The title of the Kibana Discover url attachment. Defaults to `Discover in Kibana`.

`slack_attach_opensearch_discover_url`: Enables the attachment of the `opensearch_discover_url` to the slack notification. The config `generate_opensearch_discover_url` must also be `True` in order to generate the url. Defaults to `False`.

`slack_opensearch_discover_color`: The color of the Opensearch Discover url attachment. Defaults to `#ec4b98`.

`slack_opensearch_discover_title`: The title of the Opensearch Discover url attachment. Defaults to `Discover in Opensearch`.

Example `slack_attach_kibana_discover_url`, `slack_kibana_discover_color`, `slack_kibana_discover_title`:

```
# (Required)
generate_kibana_discover_url: True
kibana_discover_app_url: "http://localhost:5601/app/discover#/"
kibana_discover_index_pattern_id: "4babf380-c3b1-11eb-b616-1b59c2feec54"
kibana_discover_version: "7.15"

# (Optional)
```

(continues on next page)

(continued from previous page)

```

kibana_discover_from_timedelta:
  minutes: 10
kibana_discover_to_timedelta:
  minutes: 10

# (Required)
slack_attach_kibana_discover_url: True

# (Optional)
slack_kibana_discover_color: "#ec4b98"
slack_kibana_discover_title: "Discover in Kibana"

```

Example slack\_attach\_opensearch\_discover\_url, slack\_opensearch\_discover\_color, slack\_opensearch\_discover\_title:

```

# (Required)
generate_opensearch_discover_url: True
opensearch_discover_app_url: "http://localhost:5601/app/discover#/"
opensearch_discover_index_pattern_id: "4babf380-c3b1-11eb-b616-1b59c2feec54"
opensearch_discover_version: "7.15"

# (Optional)
opensearch_discover_from_timedelta:
  minutes: 10
opensearch_discover_to_timedelta:
  minutes: 10

# (Required)
slack_attach_opensearch_discover_url: True

# (Optional)
slack_opensearch_discover_color: "#ec4b98"
slack_opensearch_discover_title: "Discover in opensearch"

```

slack\_ca\_certs: Set this option to True or a path to a CA cert bundle or directory (eg: /etc/ssl/certs/ca-certificates.crt) to validate the SSL certificate.

slack\_footer: Add a static footer text for alert. Defaults to "".

slack\_footer\_icon: A Public Url for a footer icon. Defaults to "".

slack\_image\_url: An optional URL to an image file (GIF, JPEG, PNG, BMP, or SVG). Defaults to "".

slack\_thumb\_url: An optional URL to an image file (GIF, JPEG, PNG, BMP, or SVG) that is displayed as thumbnail. Defaults to "".

slack\_author\_name: An optional name used to identify the author. Defaults to "".

slack\_author\_link: An optional URL used to hyperlink the author\_name. Defaults to "".

slack\_author\_icon: An optional URL used to display a 16x16 pixel icon beside the author\_name. Defaults to "".

slack\_msg\_pretext: You can set the message attachment pretext using this option. Defaults to "".

slack\_attach\_jira\_ticket\_url: Add url to the jira ticket created. Only works if the Jira alert runs before Slack alert. Set the field to True in order to generate the url. Defaults to False.

slack\_jira\_ticket\_color: The color of the Jira Ticket url attachment. Defaults to #ec4b98.

`slack_jira_ticket_title`: The title of the Jira Ticket url attachment. Defaults to Jira Ticket.

### 6.4.32 Splunk On-Call (Formerly VictorOps)

Splunk On-Call (Formerly VictorOps) alerter will trigger an incident to a predefined Splunk On-Call (Formerly VictorOps) routing key. The body of the notification is formatted the same as with other alerters.

The alerter requires the following options:

`victorops_api_key`: API key generated under the 'REST Endpoint' in the Integrations settings.

`victorops_routing_key`: Splunk On-Call (Formerly VictorOps) routing key to route the alert to.

`victorops_message_type`: Splunk On-Call (Formerly VictorOps) field to specify severity level. Must be one of the following: INFO, WARNING, ACKNOWLEDGEMENT, CRITICAL, RECOVERY

Optional:

`victorops_entity_id`: The identity of the incident used by Splunk On-Call (Formerly VictorOps) to correlate incidents throughout the alert lifecycle. If not defined, Splunk On-Call (Formerly VictorOps) will assign a random string to each alert.

`victorops_entity_display_name`: Human-readable name of alerting entity to summarize incidents without affecting the life-cycle workflow. Will use `alert_subject` if not set.

`victorops_proxy`: By default ElastAlert 2 will not use a network proxy to send notifications to Splunk On-Call (Formerly VictorOps). Set this option using `hostname:port` if you need to use a proxy. only supports https.

Example usage:

```
alert:
  - "victorops"
victorops_api_key: "VictorOps API Key"
victorops_routing_key: "VictorOps routing Key"
victorops_message_type: "INFO"
```

### 6.4.33 Stomp

This alert type will use the STOMP protocol in order to push a message to a broker like ActiveMQ or RabbitMQ. The message body is a JSON string containing the alert details. The default values will work with a pristine ActiveMQ installation.

The alerter requires the following options:

`stomp_hostname`: The STOMP host to use, defaults to localhost.

`stomp_hostport`: The STOMP port to use, defaults to 61613.

`stomp_login`: The STOMP login to use, defaults to admin.

`stomp_password`: The STOMP password to use, defaults to admin.

Optional:

`stomp_destination`: The STOMP destination to use, defaults to `/queue/ALERT`

The `stomp_destination` field depends on the broker, the `/queue/ALERT` example is the nomenclature used by ActiveMQ. Each broker has its own logic.

Example usage:

```
alert:
  - "stomp"
stomp_hostname: "localhost"
stomp_hostport: "61613"
stomp_login: "admin"
stomp_password: "admin"
stomp_destination: "/queue/ALERT"
```

### 6.4.34 Telegram

Telegram alerter will send a notification to a predefined Telegram username or channel. The body of the notification is formatted the same as with other alerters.

The alerter requires the following two options:

**telegram\_bot\_token:** The token is a string along the lines of `110201543:AAHdqTcvCH1vGWJxfSeofSAs0K5PALDsaw` that will be required to authorize the bot and send requests to the Bot API. You can learn about obtaining tokens and generating new ones in this document <https://core.telegram.org/bots#6-botfather>

**telegram\_room\_id:** Unique identifier for the target chat or username of the target channel using telegram `chat_id` (in the format “-xxxxxxx”)

Optional:

**telegram\_api\_url:** Custom domain to call Telegram Bot API. Default to `api.telegram.org`

**telegram\_proxy:** By default ElastAlert 2 will not use a network proxy to send notifications to Telegram. Set this option using `hostname:port` if you need to use a proxy. only supports https.

**telegram\_proxy\_login:** The Telegram proxy auth username.

**telegram\_proxy\_pass:** The Telegram proxy auth password.

**telegram\_parse\_mode:** The Telegram parsing mode, which determines the format of the alert text body. Possible values are `markdown`, `markdownV2`, `html`. Defaults to `markdown`.

**telegram\_thread\_id:** Unique identifier for the target thread of supergroup/forum using telegram `message_thread_id` (Optional, positive integer value, no default).

Example usage:

```
alert:
  - "telegram"
telegram_bot_token: "bot_token"
telegram_room_id: "chat_id"
```

### 6.4.35 Tencent SMS

Required:

**tencent\_sms\_secret\_id:** SecretID is used to identify the API caller.

**tencent\_sms\_secret\_key:** SecretKey is used to encrypt the string to sign that can be verified on the server. You should keep it private and avoid disclosure.

**tencent\_sms\_sdk\_appid:** SMS application ID, which is the *SdkAppId* generated after an application is added in the [SMS console](#), such as 1400006666

`tencent_sms_to_number`: Target mobile number in the E.164 standard (+[country/region code][mobile number])

Example: +8613711112222, which has a + sign followed by 86 (country/region code) and then by 13711112222 (mobile number). Up to 200 mobile numbers are supported

`tencent_sms_template_id`: Template ID. You must enter the ID of an approved template, which can be viewed in the [SMS console](#).

If you need to send SMS messages to global mobile numbers, you can only use a Global SMS template.

Optional:

`tencent_sms_sign_name`: Content of the SMS signature, which should be encoded in UTF-8. You must enter an approved signature, such as Tencent Cloud. The signature information can be viewed in the SMS console. Note: this parameter is required for Mainland China SMS.

`tencent_sms_region`: Region parameter, which is used to identify the region([Mainland China](#) or [Global](#)) to which the data you want to work with belongs.

`tencent_sms_template_parm`: The number of template parameters needs to be consistent with the number of variables of the template corresponding to TemplateId. this value format by [rfc6901](#)

```
{
  "_index" : "tmec"
  "_type" : "fluentd",
  "_id" : "PeXLrnsBvusb3d0w6dU1",
  "_score" : 1.0,

```

### 6.4.36 TheHive

TheHive alerter can be used to create a new alert in TheHive. The alerter supports adding tags, custom fields, and observables from the alert matches and rule data.

Required:

**hive\_connection:** The connection details to your instance (see example below for the required syntax). Only **hive\_apikey** is required, **hive\_host** and **hive\_port** default to `http://localhost` and `9000` respectively.

**hive\_alert\_config:** Configuration options for the alert, see example below for structure.

**source:** Text content to use for TheHive event's "source" field. See the optional **source\_args** parameter for dynamically formatting this content with dynamic lookup values.

**type** Text content to use for TheHive event's "type" field. See the optional **type\_args** parameter for dynamically formatting this content with dynamic lookup values.

Optional:

**tags** can be populated from the matched record, using the same syntax used in **alert\_text\_args**. If a record doesn't contain the specified value, the rule itself will be examined for the tag. If this doesn't contain the tag either, the tag is attached without modification to the alert. For aggregated alerts, all matches are examined individually, and tags generated for each one. All tags are then attached to the same alert.

**customFields** can also be populated from rule fields as well as matched results. Custom fields are only populated once. If an alert is an aggregated alert, the custom field values will be populated using the first matched record, before checking the rule. If neither matches, the **customField.value** will be used directly.

**hive\_observable\_data\_mapping:** If needed, matched data fields can be mapped to TheHive observable types using the same syntax as **customFields**, described above. The algorithm used to populate the observable value is similar to the one used to populate the **tags**, including the behaviour for aggregated alerts. The **tlp**, **message**, and **tags** fields are optional for each observable. If not specified, the **tlp** field is given a default value of 2.

**hive\_proxies:** Proxy configuration.

**hive\_verify:** Whether or not to enable SSL certificate validation. Defaults to False.

**description\_args:** can be used to format the description field with additional rule and match field lookups. Note that the description will be initially populated from the ElastAlert 2 default **alert\_text** fields, including any defined **alert\_text\_args**. See the "Alert Content" section for more information on the default formatting.

**description\_missing\_value:** Text to replace any match field not found when formatting the **description**. Defaults to `<MISSING VALUE>`.

**source\_args:** List of parameters to format into the **source** text content, with values originating from the first match event.

**title:** Text content to use for TheHive event's "title" field. This will override the default alert title generated from the **alert\_subject** and associated **arg** parameters. See the "Alert Subject" section for more information on the default formatting.

**title\_args:** List of additional args to format against the "title" content. If the title argument is not provided then these optional arguments will be formatted against the already formatted title generated from the **alert\_subject** and related parameters. This means that a two-phased formatting potentially could be utilized in very specific configuration scenarios. See the "Alert Subject" section for more information on the default formatting. The values will be used from the first match event.

**type\_args:** List of parameters to format into the **type** text content, with values originating from the first match event.

Example usage:

```

alert: hivealerter

hive_connection:
  hive_host: http://localhost
  hive_port: <hive_port>
  hive_apikey: <hive_apikey>
  hive_proxies:
    http: ''
    https: ''

hive_alert_config:
  customFields:
    - name: example
      type: string
      value: example
  follow: True
  severity: 2
  status: 'New'
  source: 'src-{}'
  source_args: [ data.source ]
  description_args: [ name, description]
  description: '{0} : {1}'
  tags: ['tag1', 'tag2']
  title: 'Title {}'
  title_args: [ data.title ]
  tlp: 3
  type: 'type-{}'
  type_args: [ data.type ]

hive_observable_data_mapping:
  - domain: agent.hostname
    tlp: 1
    tags: ['tag1', 'tag2']
    message: 'agent hostname'
  - domain: response.domain
    tlp: 2
    tags: ['tag3']
  - ip: client.ip

```

### 6.4.37 Twilio

The Twilio alerter will send an alert to a mobile phone as an SMS from your Twilio phone number. The SMS will contain the alert name. You may use either Twilio SMS or Twilio Copilot to send the message, controlled by the `twilio_use_copilot` option.

Note that when Twilio Copilot *is* used the `twilio_message_service_sid` option is required. Likewise, when *not* using Twilio Copilot, the `twilio_from_number` option is required.

The alerter requires the following options:

`twilio_account_sid`: The SID of your Twilio account.

`twilio_auth_token`: Auth token associated with your Twilio account.

`twilio_to_number`: The phone number where you would like to send the alert.

Either one of

- `twilio_from_number`: The Twilio phone number from which the alert will be sent.
- `twilio_message_service_sid`: The SID of your Twilio message service.

Optional:

`twilio_use_copilot`: Whether or not to use Twilio Copilot, False by default.

Example with Copilot usage:

```
alert:
  - "twilio"
twilio_use_copilot: True
twilio_to_number: "0123456789"
twilio_auth_token: "abcdefghijklmnopqrstuvwxyz012345"
twilio_account_sid: "ABCDEFGHIJKLMNOPQRSTUVWXYZ01234567"
twilio_message_service_sid: "ABCDEFGHIJKLMNOPQRSTUVWXYZ01234567"
```

Example with SMS usage:

```
alert:
  - "twilio"
twilio_to_number: "0123456789"
twilio_from_number: "9876543210"
twilio_auth_token: "abcdefghijklmnopqrstuvwxyz012345"
twilio_account_sid: "ABCDEFGHIJKLMNOPQRSTUVWXYZ01234567"
```

### 6.4.38 WorkWechat

WorkWechat alerter will send notification to a predefined bot in WorkWechat application. The body of the notification is formatted the same as with other alerters.

Required:

`work_wechat_bot_id`: WorkWechat bot id. `work_wechat_msgtype`: WorkWechat msgtype. default to `text`. `markdown`

Example usage:

```
alert:
  - "workwechat"
work_wechat_bot_id: "your workwechat bot id"
work_wechat_msgtype: "text"
```

### 6.4.39 Zabbix

Zabbix will send notification to a Zabbix server. The item in the host specified receive a 1 value for each hit. For example, if the elastic query produce 3 hits in the last execution of ElastAlert 2, three '1' (integer) values will be send from elastalert to Zabbix Server. If the query have 0 hits, any value will be sent.

Required:

`zbx_sender_host`: The address where zabbix server is running, defaults to 'localhost'.

`zbx_sender_port`: The port where zabbix server is listenning, defaults to 10051.

`zbx_host_from_field`: This field allows to specify `zbx_host` value from the available terms. Defaults to `False`.

`zbx_host`: This field setup the host in zabbix that receives the value sent by ElastAlert 2.

`zbx_key`: This field setup the key in the host that receives the value sent by ElastAlert 2.

Example usage:

```
alert:
  - "zabbix"
zbx_sender_host: "zabbix-server"
zbx_sender_port: 10051
zbx_host: "test001"
zbx_key: "sender_load1"
```

To specify `zbx_host` depending on the available elasticsearch field, zabbix alerter has `zbx_host_from_field` option.

Example usage:

```
alert:
  - "zabbix"
zbx_sender_host: "zabbix-server"
zbx_sender_port: 10051
zbx_host_from_field: True
zbx_host: "hostname"
zbx_key: "sender_load1"
```

where `hostname` is the available elasticsearch field.

## LOGGING

By default, ElastAlert 2 uses a simple basic logging configuration to print log messages to standard error. You can change the log level to INFO messages by using the `--verbose` or `--debug` command line options.

If you need a more sophisticated logging configuration, you can provide a full logging configuration in the config file. This way you can also configure logging to a file, to Logstash and adjust the logging format.

For details, see the end of `examples/config.yaml.example` where you can find an example logging configuration.

## ADVANCED TOPICS

The following documentation is available for additional topics for users looking to learn more about ElastAlert 2.

### 8.1 Writing Filters For Rules

This document describes how to create a filter section for your rule config file.

The filters used in rules are part of the Elasticsearch query DSL, further documentation for which can be found at <https://www.elastic.co/guide/en/elasticsearch/reference/current/query-dsl.html> This document contains a small subset of particularly useful filters.

The filter section is passed to Elasticsearch exactly as follows:

```
filter:
  and:
    filters:
      - [filters from rule.yaml]
```

Every result that matches these filters will be passed to the rule for processing.

#### 8.1.1 Common Filter Types:

##### query\_string

The query\_string type follows the Lucene query format and can be used for partial or full matches to multiple fields. See [http://lucene.apache.org/core/2\\_9\\_4/queryparsersyntax.html](http://lucene.apache.org/core/2_9_4/queryparsersyntax.html) for more information:

```
filter:
- query:
  query_string:
    query: "username: bob"
- query:
  query_string:
    query: "_type: login_logs"
- query:
  query_string:
    query: "field: value OR otherfield: othervalue"
- query:
  query_string:
    query: "this: that AND these: those"
```

### term

The term type allows for exact field matches:

```
filter:
- term:
  name_field: "bob"
- term:
  _type: "login_logs"
```

Note that a term query may not behave as expected if a field is analyzed. By default, many string fields will be tokenized by whitespace, and a term query for “foo bar” may not match a field that appears to have the value “foo bar”, unless it is not analyzed. Conversely, a term query for “foo” will match analyzed strings “foo bar” and “foo baz”. For full text matching on analyzed fields, use `query_string`. See <https://www.elastic.co/guide/en/elasticsearch/guide/current/term-vs-full-text.html>

### terms

Terms allows for easy combination of multiple term filters:

```
filter:
- terms:
  field: ["value1", "value2"] # value1 OR value2
```

You can also match on multiple fields (All terms must match at least one of the given values):

```
- terms:
  fieldX: ["value1", "value2"]
- terms:
  fieldY: ["something", "something_else"]
- terms:
  fieldZ: ["foo", "bar", "baz"]
```

### wildcard

For wildcard matches:

```
filter:
- query:
  wildcard:
    field: "foo*bar"
```

### range

For ranges on fields:

```
filter:
- range:
  status_code:
    from: 500
    to: 599
```

## Negation, and, or

Below is a more complex example for Elasticsearch 7.x, provided by a [community user](#):

```
filter:
- term:
  action: order
- terms:
  dining:
    - pickup
    - delivery
- bool:
  #exclude common/expected orders
  must_not:
    #Alice usually gets a pizza
    - bool:
      must: [ {term: {uid: alice}}, {term: {menu_item: pizza}} ]
    #Bob loves his hoagies
    - bool:
      must: [ {term: {uid: bob}}, {term: {menu_item: sandwich}} ]
    #Charlie has a few favorites
    - bool:
      must:
        - term:
          uid: charlie
        - match:
          menu_item: "burrito pasta salad pizza"
```

## EQL (Event Query Language)

EQL is partially supported as of version 2.12.0. To use EQL, include a filter item as follows:

```
filter:
- eql: any where machine.os == "win 8"
```

Note that only one eql filter can be defined in a filter.

It is also possible to use standard query filters in combination with EQL filters:

```
filter:
- eql: any where machine.os == "win 8"
- query:
  query_string:
    query: "test.field: 123"
```

EQL is only partially supported due to the following limitations:

- Cannot be used with aggregation rule types.
- Cannot be used with blacklist/whitelist rule types.
- Cannot be used with percentage match rule types.
- Cannot be used with use\_count\_query property.

- Does not support scrolling, so large result sets may have unexpected results. Be sure to filter your queries thoroughly to avoid returning excessive numbers of events.
- Not supported with OpenSearch

## 8.2 Extending ElastAlert 2

ElastAlert 2 offers a variety of ways to extend the functionality. This includes adding your own rules, your own alerts, rule loaders, etc.

### 8.2.1 Adding a New Rule Type

This document describes how to create a new rule type. Built in rule types live in `elastalert/ruletypes.py` and are subclasses of `RuleType`. At the minimum, your rule needs to implement `add_data`.

Your class may implement several functions from `RuleType`:

```
class AwesomeNewRule(RuleType):
    # ...
    def add_data(self, data):
        # ...
    def get_match_str(self, match):
        # ...
    def garbage_collect(self, timestamp):
        # ...
```

You can import new rule types by specifying the type as `module.file.RuleName`, where `module` is the name of a Python module, or folder containing `__init__.py`, and `file` is the name of the Python file containing a `RuleType` subclass named `RuleName`.

### Basics

The `RuleType` instance remains in memory while ElastAlert is running, receives data, keeps track of its state, and generates matches. Several important member properties are created in the `__init__` method of `RuleType`:

`self.rules`: This dictionary is loaded from the rule configuration file. If there is a `timeframe` configuration option, this will be automatically converted to a `datetime.timedelta` object when the rules are loaded.

`self.matches`: This is where ElastAlert 2 checks for matches from the rule. Whatever information is relevant to the match (generally coming from the fields in Elasticsearch) should be put into a dictionary object and added to `self.matches`. ElastAlert 2 will pop items out periodically and send alerts based on these objects. It is recommended that you use `self.add_match(match)` to add matches. In addition to appending to `self.matches`, `self.add_match` will convert the `datetime @timestamp` back into an ISO8601 timestamp.

`self.required_options`: This is a set of options that must exist in the configuration file. ElastAlert 2 will ensure that all of these fields exist before trying to instantiate a `RuleType` instance.

**add\_data(self, data):**

When ElastAlert 2 queries Elasticsearch, it will pass all of the hits to the rule type by calling `add_data`. `data` is a list of dictionary objects which contain all of the fields in `include`, `query_key` and `compare_key` if they exist, and `@timestamp` as a datetime object. They will always come in chronological order sorted by `'@timestamp'`.

**get\_match\_str(self, match):**

Alerts will call this function to get a human readable string about a match for an alert. Match will be the same object that was added to `self.matches`, and rules the same as `self.rules`. The `RuleType` base implementation will return an empty string. Note that by default, the alert text will already contain the key-value pairs from the match. This should return a string that gives some information about the match in the context of this specific `RuleType`.

**garbage\_collect(self, timestamp):**

This will be called after ElastAlert 2 has run over a time period ending in `timestamp` and should be used to clear any state that may be obsolete as of `timestamp`. `timestamp` is a datetime object.

**Tutorial**

As an example, we are going to create a rule type for detecting suspicious logins. Let's imagine the data we are querying is login events that contains IP address, username and a timestamp. Our configuration will take a list of usernames and a time range and alert if a login occurs in the time range. First, let's create a modules folder in the base ElastAlert 2 folder:

```
$ mkdir elastalert_modules
$ cd elastalert_modules
$ touch __init__.py
```

Now, in a file named `my_rules.py`, add

```
import dateutil.parser

from elastalert.ruletypes import RuleType

# elastalert.util includes useful utility functions
# such as converting from timestamp to datetime obj
from elastalert.util import ts_to_dt

class AwesomeRule(RuleType):

    # By setting required_options to a set of strings
    # You can ensure that the rule config file specifies all
    # of the options. Otherwise, ElastAlert 2 will throw an exception
    # when trying to load the rule.
    required_options = set(['time_start', 'time_end', 'usernames'])

    # add_data will be called each time Elasticsearch is queried.
    # data is a list of documents from Elasticsearch, sorted by timestamp,
    # including all the fields that the config specifies with "include"
    def add_data(self, data):
```

(continues on next page)

(continued from previous page)

```

for document in data:

    # To access config options, use self.rules
    if document['username'] in self.rules['usernames']:

        # Convert the timestamp to a time object
        login_time = document['@timestamp'].time()

        # Convert time_start and time_end to time objects
        time_start = dateutil.parser.parse(self.rules['time_start']).time()
        time_end = dateutil.parser.parse(self.rules['time_end']).time()

        # If the time falls between start and end
        if login_time > time_start and login_time < time_end:

            # To add a match, use self.add_match
            self.add_match(document)

    # The results of get_match_str will appear in the alert text
    def get_match_str(self, match):
        return "%s logged in between %s and %s" % (match['username'],
                                                    self.rules['time_start'],
                                                    self.rules['time_end'])

    # garbage_collect is called indicating that ElastAlert 2 has already been run up to
    ↪ timestamp
    # It is useful for knowing that there were no query results from Elasticsearch
    ↪ because
    # add_data will not be called with an empty list
    def garbage_collect(self, timestamp):
        pass

```

In the rule configuration file, `examples/rules/example_login_rule.yaml`, we are going to specify this rule by writing

```

name: "Example login rule"
es_host: elasticsearch.example.com
es_port: 14900
type: "elastalert_modules.my_rules.AwesomeRule"
# Alert if admin, userXYZ or foobaz log in between 8 PM and midnight
time_start: "20:00"
time_end: "24:00"
usernames:
- "admin"
- "userXYZ"
- "foobaz"
# We require the username field from documents
include:
- "username"
alert:
- debug

```

ElastAlert 2 will attempt to import the rule with `from elastalert_modules.my_rules import AwesomeRule`.

This means that the folder must be in a location where it can be imported as a Python module.

An alert from this rule will look something like:

Example login rule

userXYZ logged in between 20:00 and 24:00

@timestamp: 2015-03-02T22:23:24Z

username: userXYZ

## 8.2.2 Adding a New Alerter

Alerters are subclasses of `Alerter`, found in `elastalert/alerts.py`. They are given matches and perform some action based on that. Your alerter needs to implement two member functions, and will look something like this:

```
class AwesomeNewAlerter(Alerter):
    required_options = set(['some_config_option'])
    def alert(self, matches):
        ...
    def get_info(self):
        ...
```

You can import alert types by specifying the type as `module.file.AlertName`, where `module` is the name of a python module, and `file` is the name of the python file containing a `Alerter` subclass named `AlertName`.

### Basics

The alerter class will be instantiated when ElastAlert 2 starts, and be periodically passed matches through the `alert` method. ElastAlert 2 also writes back info about the alert into Elasticsearch that it obtains through `get_info`. Several important member properties:

`self.required_options`: This is a set containing names of configuration options that must be present. ElastAlert 2 will not instantiate the alert if any are missing.

`self.rule`: The dictionary containing the rule configuration. All options specific to the alert should be in the rule configuration file and can be accessed here.

`self.pipeline`: This is a dictionary object that serves to transfer information between alerts. When an alert is triggered, a new empty pipeline object will be created and each alerter can add or receive information from it. Note that alerters are called in the order they are defined in the rule file. For example, the Jira alerter will add its ticket number to the pipeline and the email alerter will add that link if it's present in the pipeline.

### `alert(self, match):`

ElastAlert 2 will call this function to send an alert. `matches` is a list of dictionary objects with information about the match. You can get a nice string representation of the match by calling `self.rule['type'].get_match_str(match, self.rule)`. If this method raises an exception, it will be caught by ElastAlert 2 and the alert will be marked as unsent and saved for later.

### get\_info(self):

This function is called to get information about the alert to save back to Elasticsearch. It should return a dictionary, which is uploaded directly to Elasticsearch, and should contain useful information about the alert such as the type, recipients, parameters, etc.

## Tutorial

Let's create a new alert that will write alerts to a local output file. First, create a modules folder in the base ElastAlert 2 folder:

```
$ mkdir elastalert_modules
$ cd elastalert_modules
$ touch __init__.py
```

Now, in a file named `my_alerts.py`, add

```
from elastalert.alerts import Alerter, BasicMatchString

class AwesomeNewAlerter(Alerter):

    # By setting required_options to a set of strings
    # You can ensure that the rule config file specifies all
    # of the options. Otherwise, ElastAlert 2 will throw an exception
    # when trying to load the rule.
    required_options = set(['output_file_path'])

    # Alert is called
    def alert(self, matches):

        # Matches is a list of match dictionaries.
        # It contains more than one match when the alert has
        # the aggregation option set
        for match in matches:

            # Config options can be accessed with self.rule
            with open(self.rule['output_file_path'], "a") as output_file:

                # basic_match_string will transform the match into the default
                # human readable string format
                match_string = str(BasicMatchString(self.rule, match))

                output_file.write(match_string)

    # get_info is called after an alert is sent to get data that is written back
    # to Elasticsearch in the field "alert_info"
    # It should return a dict of information relevant to what the alert does
    def get_info(self):
        return {'type': 'Awesome Alerter',
                'output_file': self.rule['output_file_path']}
```

In the rule configuration file, we are going to specify the alert by writing

```
alert: "elastalert_modules.my_alerts.AwesomeNewAlerter"
output_file_path: "/tmp/alerts.log"
```

ElastAlert 2 will attempt to import the alert with `from elastalert_modules.my_alerts import AwesomeNewAlerter`. This means that the folder must be in a location where it can be imported as a python module.

### 8.2.3 Enhancements

Enhancements are modules which let you modify a match before an alert is sent. They should subclass `BaseEnhancement`, found in `elastalert/enhancements.py`. They can be added to rules using the `match_enhancements` option:

```
match_enhancements:
- module.file.MyEnhancement
```

where `module` is the name of a Python module, or folder containing `__init__.py`, and `file` is the name of the Python file containing a `BaseEnhancement` subclass named `MyEnhancement`.

A special exception class `DropMatchException` can be used in enhancements to drop matches if custom conditions are met. For example:

```
class MyEnhancement(BaseEnhancement):
    def process(self, match):
        # Drops a match if "field_1" == "field_2"
        if match['field_1'] == match['field_2']:
            raise DropMatchException()
```

### Example

As an example enhancement, let's add a link to a whois website. The match must contain a field named `domain` and it will add an entry named `domain_whois_link`. First, create a `modules` folder for the enhancement in the ElastAlert 2 directory.

```
$ mkdir elastalert_modules
$ cd elastalert_modules
$ touch __init__.py
```

Now, in a file named `my_enhancements.py`, add

```
from elastalert.enhancements import BaseEnhancement

class MyEnhancement(BaseEnhancement):

    # The enhancement is run against every match
    # The match is passed to the process function where it can be modified in any way
    # ElastAlert 2 will do this for each enhancement linked to a rule
    def process(self, match):
        if 'domain' in match:
            url = "http://who.is/whois/%s" % (match['domain'])
            match['domain_whois_link'] = url
```

Enhancements will not automatically be run. Inside the rule configuration file, you need to point it to the enhancement(s) that it should run by setting the `match_enhancements` option:

```
match_enhancements:
- "elastalert_modules.my_enhancements.MyEnhancement"
```

## 8.2.4 Rules Loaders

RulesLoaders are subclasses of `RulesLoader`, found in `elastalert/loaders.py`. They are used to gather rules for a particular source. Your `RulesLoader` needs to implement three member functions, and will look something like this:

```
class AwesomeNewRulesLoader(RulesLoader):
    def get_names(self, conf, use_rule=None):
        ...

    def get_hashes(self, conf, use_rule=None):
        ...

    def get_yaml(self, rule):
        ...
```

You can import loaders by specifying the type as `module.file.RulesLoaderName`, where `module` is the name of a python module, and `file` is the name of the python file containing a `RulesLoader` subclass named `RulesLoaderName`.

### Example

As an example loader, let's retrieve rules from a database rather than from the local file system. First, create a `modules` folder for the loader in the ElastAlert 2 directory.

```
$ mkdir elastalert_modules
$ cd elastalert_modules
$ touch __init__.py
```

Now, in a file named `mongo_loader.py`, add

```
from pymongo import MongoClient
from elastalert.loaders import RulesLoader
import yaml

class MongoRulesLoader(RulesLoader):
    def __init__(self, conf):
        super(MongoRulesLoader, self).__init__(conf)
        self.client = MongoClient(conf['mongo_url'])
        self.db = self.client[conf['mongo_db']]
        self.cache = {}

    def get_names(self, conf, use_rule=None):
        if use_rule:
            return [use_rule]

        rules = []
        self.cache = {}
        for rule in self.db.rules.find():
            self.cache[rule['name']] = yaml.load(rule['yaml'])
```

(continues on next page)

(continued from previous page)

```

        rules.append(rule['name'])

    return rules

def get_hashes(self, conf, use_rule=None):
    if use_rule:
        return [use_rule]

    hashes = {}
    self.cache = {}
    for rule in self.db.rules.find():
        self.cache[rule['name']] = rule['yaml']
        hashes[rule['name']] = rule['hash']

    return hashes

def get_yaml(self, rule):
    if rule in self.cache:
        return self.cache[rule]

    self.cache[rule] = yaml.load(self.db.rules.find_one({'name': rule})['yaml'])
    return self.cache[rule]

```

Finally, you need to specify in your ElastAlert 2 configuration file that MongoRulesLoader should be used instead of the default FileRulesLoader, so in your `elastalert.conf` file:

```
rules_loader: "elastalert_modules.mongo_loader.MongoRulesLoader"
```

## 8.3 ElastAlert 2 Metadata Index

ElastAlert 2 uses Elasticsearch to store various information about its state. This not only allows for some level of auditing and debugging of ElastAlert 2's operation, but also to avoid loss of data or duplication of alerts when ElastAlert 2 is shut down, restarted, or crashes. This cluster and index information is defined in the global config file with `es_host`, `es_port` and `writeback_index`. ElastAlert 2 must be able to write to this index. The script, `elastalert-create-index` will create the index with the correct mapping for you, and optionally copy the documents from an existing ElastAlert 2 writeback index. Run it and it will prompt you for the cluster information.

ElastAlert 2 will create three different types of documents in the writeback index:

### 8.3.1 elastalert\_status

`elastalert_status` is a log of the queries performed for a given rule and contains:

- `@timestamp`: The time when the document was uploaded to Elasticsearch. This is after a query has been run and the results have been processed.
- `rule_name`: The name of the corresponding rule.
- `starttime`: The beginning of the timestamp range the query searched.
- `endtime`: The end of the timestamp range the query searched.
- `hits`: The number of results from the query.

- **matches:** The number of matches that the rule returned after processing the hits. Note that this does not necessarily mean that alerts were triggered.
- **time\_taken:** The number of seconds it took for this query to run.

`elastalert_status` is what ElastAlert 2 will use to determine what time range to query when it first starts to avoid duplicating queries. For each rule, it will start querying from the most recent endtime. If ElastAlert 2 is running in debug mode, it will still attempt to base its start time by looking for the most recent search performed, but it will not write the results of any query back to Elasticsearch.

### 8.3.2 elastalert

`elastalert` is a log of information about every alert triggered and contains:

- **@timestamp:** The time when the document was uploaded to Elasticsearch. This is not the same as when the alert was sent, but rather when the rule outputs a match.
- **rule\_name:** The name of the corresponding rule.
- **alert\_info:** This contains the output of `Alert.get_info`, a function that alerts implement to give some relevant context to the alert type. This may contain `alert_info.type`, `alert_info.recipient`, or any number of other sub fields.
- **alert\_sent:** A boolean value as to whether this alert was actually sent or not. It may be false in the case of an exception or if it is part of an aggregated alert.
- **alert\_time:** The time that the alert was or will be sent. Usually, this is the same as `@timestamp`, but may be some time in the future, indicating when an aggregated alert will be sent.
- **match\_body:** This is the contents of the match dictionary that is used to create the alert. The subfields may include a number of things containing information about the alert.
- **alert\_exception:** This field is only present when the alert failed because of an exception occurring, and will contain the exception information.
- **aggregate\_id:** This field is only present when the rule is configured to use aggregation. The first alert of the aggregation period will contain an `alert_time` set to the aggregation time into the future, and subsequent alerts will contain the document ID of the first. When the `alert_time` is reached, all alerts with that `aggregate_id` will be sent together.

### 8.3.3 elastalert\_error

When an error occurs in ElastAlert 2, it is written to both Elasticsearch and to `stderr`. The `elastalert_error` type contains:

- **@timestamp:** The time when the error occurred.
- **message:** The error or exception message.
- **traceback:** The traceback from when the error occurred.
- **data:** Extra information about the error. This often contains the name of the rule which caused the error.

### 8.3.4 silence

`silence` is a record of when alerts for a given rule will be suppressed, either because of a `realert` setting or from using `-silence`. When an alert with `realert` is triggered, a `silence` record will be written with `until` set to the alert time plus `realert`.

- `@timestamp`: The time when the document was uploaded to Elasticsearch.
- `rule_name`: The name of the corresponding rule.
- `until`: The timestamp when alerts will begin being sent again.
- `exponent`: The exponential factor which multiplies `realert`. The length of this silence is equal to `realert * 2**exponent`. This will be 0 unless `exponential_realert` is set.

Whenever an alert is triggered, ElastAlert 2 will check for a matching `silence` document, and if the `until` timestamp is in the future, it will ignore the alert completely. See the *Running ElastAlert 2* section for information on how to silence an alert.

## 8.4 Elasticsearch Security Privileges

While ElastAlert 2 will just work out-of-the-box for unsecured Elasticsearch, it will need a user with a certain set of permissions to work on secure Elasticsearch that allow it to read the documents, check the cluster status etc.

### 8.4.1 SearchGuard Permissions

The permissions in Elasticsearch are specific to the plugin being used for RBAC. However, the permissions mentioned here can be mapped easily to different plugins other than Searchguard.

Details about SearchGuard Action Groups: <https://docs.search-guard.com/latest/action-groups>

#### Writeback Permissions

For the global config (which writes to the writeback index), you would need to give all permissions on the writeback indices. In addition, some permissions related to Cluster Monitor Access are required.

Cluster Permissions: `CLUSTER_MONITOR`, `indices:data/read/scroll*`

Index Permissions (Over Writeback Indices): `INDICES_ALL`

#### Per Rule Permissions

For per rule Elasticsearch config, you would need at least the read permissions on the index you want to query. Detailed SearchGuard Permissions:

Cluster Permissions: `CLUSTER_COMPOSITE_OPS_RO`

Index Permissions (Over the index the rule is querying on): `READ`, `indices:data/read/scroll*`

## 8.5 Exposing Rule Metrics

### 8.5.1 Configuration

Running ElastAlert with `--prometheus_port` configuration flag will expose ElastAlert 2 Prometheus metrics on the specified port. Prometheus metrics are disabled by default.

To expose ElastAlert rule metrics on port 9979 run the following command:

```
$ elastalert --config config.yaml --prometheus_port 9979
```

### 8.5.2 Rule Metrics

The metrics being exposed are related to the [ElastAlert 2 metadata indices](#). The exposed metrics are in the [Prometheus text-based format](#). Metrics are of the metric type [counter](#) or [gauge](#) and follow the [Prometheus metric naming](#).

In the standard metric definition, the metric names are structured as follows:

```
elastalert_{metric}_{unit}
```

Where:

- `{metric}` is a unique name of the metric. For example, `hits`.
- `{unit}` is the unit of measurement of the metric value. For example, `total` is a counter type metric and `created` is a gauge type metric.

All metrics except `elastalert_errors_{unit}` have values that apply to a particular rule name. In the exported metrics, these can be identified using the `rule_name` [Prometheus label](#).

Find below all available metrics:

METRIC	Type	Description	Label
<code>elastalert_scrapes_{unit}</code>	Counter, Gauge	Number of scrapes	<code>rule_name</code>
<code>elastalert_hits_{unit}</code>	Counter, Gauge	Number of hits	<code>rule_name</code>
<code>elastalert_matches_{unit}</code>	Counter, Gauge	Number of matches	<code>rule_name</code>
<code>elastalert_time_taken_{unit}</code>	Counter, Gauge	Time taken in seconds	<code>rule_name</code>
<code>elastalert_alerts_sent_{unit}</code>	Counter, Gauge	Number of alerts sent	<code>rule_name</code>
<code>elastalert_alerts_not_sent_{unit}</code>	Counter, Gauge	Number of alerts not sent	<code>rule_name</code>
<code>elastalert_alerts_silenced_{unit}</code>	Counter, Gauge	Number of silenced alerts	<code>rule_name</code>
<code>elastalert_errors_{unit}</code>	Counter, Gauge	Number of errors	

## 8.6 OpenSearch

ElastAlert 2 supports Amazon OpenSearch. In general ElastAlert 2 will auto-detect OpenSearch and make adjustments internally to handle the differences between OpenSearch and Elasticsearch.

### 8.6.1 Signing requests to Amazon OpenSearch Service

When using Amazon OpenSearch Service, you need to secure your Elasticsearch from the outside. Currently, there is no way to secure your Elasticsearch using network firewall rules, so the only way is to signing the requests using the access key and secret key for a role or user with permissions on the Elasticsearch service.

You can sign requests to AWS using any of the standard AWS methods of providing credentials. - Environment Variables, `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` - AWS Config or Credential Files, `~/.aws/config` and `~/.aws/credentials` - AWS Instance Profiles, uses the EC2 Metadata service

#### Using an Instance Profile

Typically, you'll deploy ElastAlert 2 on a running EC2 instance on AWS. You can assign a role to this instance that gives it permissions to read from and write to the Elasticsearch service. When using an Instance Profile, you will need to specify the `aws_region` in the configuration file or set the `AWS_DEFAULT_REGION` environment variable.

#### Using AWS profiles

You can also create a user with permissions on the Elasticsearch service and tell ElastAlert 2 to authenticate itself using that user. First, create an AWS profile in the machine where you'd like to run ElastAlert 2 for the user with permissions.

You can use the environment variables `AWS_DEFAULT_PROFILE` and `AWS_DEFAULT_REGION` or add two options to the configuration file: - `aws_region`: The AWS region where you want to operate. - `profile`: The name of the AWS profile to use to sign the requests.

## FREQUENTLY ASKED QUESTIONS

### 9.1 My rule is not getting any hits?

So you've managed to set up ElastAlert 2, write a rule, and run it, but nothing happens, or it says `0 query hits`. First of all, we recommend using the command `elastalert-test-rule rule.yaml` to debug. It will show you how many documents match your filters for the last 24 hours (or more, see `--help`), and then shows you if any alerts would have fired. If you have a filter in your rule, remove it and try again. This will show you if the index is correct and that you have at least some documents. If you have a filter in Kibana and want to recreate it in ElastAlert 2, you probably want to use a query string. Your filter will look like

```
filter:
- query:
  query_string:
    query: "foo: bar AND baz: abc*"
```

If you receive an error that Elasticsearch is unable to parse it, it's likely the YAML is not spaced correctly, and the filter is not in the right format. If you are using other types of filters, like `term`, a common pitfall is not realizing that you may need to use the analyzed token. This is the default if you are using Logstash. For example,

```
filter:
- term:
  foo: "Test Document"
```

will not match even if the original value for `foo` was exactly "Test Document". Instead, you want to use `foo.raw`. If you are still having trouble troubleshooting why your documents do not match, try running ElastAlert 2 with `--es_debug_trace /path/to/file.log`. This will log the queries made to Elasticsearch in full so that you can see exactly what is happening.

Finally, but very important, if you have enabled role-based access control in Elasticsearch: make sure that the Elasticsearch user used by ElastAlert actually has the privileges to access the index (at least `read` permission). See [ES documentation page](<https://www.elastic.co/guide/en/elasticsearch/reference/current/authorization.html>) on the topic of user authorization.

## 9.2 I got hits, why didn't I get an alert?

If you got logs that had `X` query hits, `0` matches, `0` alerts sent, it depends on the type why you didn't get any alerts. If `type: any`, a match will occur for every hit. If you are using `type: frequency`, `num_events` must occur within `timeframe` of each other for a match to occur. Different rules apply for different rule types.

If you see `X` matches, `0` alerts sent, this may occur for several reasons. If you set `aggregation`, the alert will not be sent until after that time has elapsed. If you have gotten an alert for this same rule before, that rule may be silenced for a period of time. The default is one minute between alerts. If a rule is silenced, you will see `Ignoring match for silenced rule` in the logs.

If you see `X` alerts sent but didn't get any alert, it's probably related to the alert configuration. If you are using the `--debug` flag, you will not receive any alerts. Instead, the alert text will be written to the console. Use `--verbose` to achieve the same affects without preventing alerts. If you are using email alert, make sure you have it configured for an SMTP server. By default, it will connect to localhost on port 25. It will also use the word "elastalert" as the "From:" address. Some SMTP servers will reject this because it does not have a domain while others will add their own domain automatically. See the email section in the documentation for how to configure this.

## 9.3 Why did I only get one alert when I expected to get several?

There is a setting called `realert` which is the minimum time between two alerts for the same rule. Any alert that occurs within this time will simply be dropped. The default value for this is one minute. If you want to receive an alert for every single match, even if they occur right after each other, use

```
realert:
  minutes: 0
```

You can of course set it higher as well.

## 9.4 How can I prevent duplicate alerts?

By setting `realert`, you will prevent the same rule from alerting twice in an amount of time.

```
realert:
  days: 1
```

You can also prevent duplicates based on a certain field by using `query_key`. For example, to prevent multiple alerts for the same user, you might use

```
realert:
  hours: 8
  query_key: user
```

Note that this will also affect the way many rule types work. If you are using `type: frequency` for example, `num_events` for a single value of `query_key` must occur before an alert will be sent. You can also use a compound of multiple fields for this key. For example, if you only wanted to receive an alert once for a specific error and hostname, you could use

```
query_key: [error, hostname]
```

You can also write in the following way.

**query\_key:**

- error
- hostname

Internally, this works by creating a new field for each document called `field1`, `field2` with a value of `value1`, `value2` and using that as the `query_key`.

The data for when an alert will fire again is stored in Elasticsearch in the `elastalert_status` index, with a `_type` of `silence` and also cached in memory.

## 9.5 How can I change what's in the alert?

You can use the field `alert_text` to add custom text to an alert. By setting `alert_text_type: alert_text_only` Or `alert_text_type: alert_text_jinja`, it will be the entirety of the alert. You can also add different fields from the alert:

With `alert_text_type: alert_text_jinja` by using [Jinja2](https://pypi.org/project/Jinja2/) Template.

**alert\_text\_type:** `alert_text_jinja`

**alert\_text:** |  
 Alert triggered! \*({{num\_hits}} Matches!)\*  
 Something happened with {{username}} ({{email}})  
 {{description|truncate}}

- Top fields are accessible via `{{field_name}}` or `{{_data['field_name']}}`, `_data` is useful when accessing *fields with dots in their keys*, as Jinja treat dot as a nested field.
- If `_data` conflicts with your top level data, use `jinja_root_name` to change its name.

With `alert_text_type: alert_text_only` by using Python style string formatting and `alert_text_args`. For example

**alert\_text:** `"Something happened with {0} at {1}"`  
**alert\_text\_type:** `alert_text_only`  
**alert\_text\_args:** `["username", "@timestamp"]`

You can also limit the alert to only containing certain fields from the document by using `include`.

**include:** `["ip_address", "hostname", "status"]`

## 9.6 My alert only contains data for one event, how can I see more?

If you are using `type: frequency`, you can set the option `attach_related: true` and every document will be included in the alert. An alternative, which works for every type, is `top_count_keys`. This will show the top counts for each value for certain fields. For example, if you have

**top\_count\_keys:** `["ip_address", "status"]`

and 10 documents matched your alert, it may contain something like

```
ip_address:
127.0.0.1: 7
10.0.0.1: 2
192.168.0.1: 1

status:
200: 9
500: 1
```

## 9.7 How can I make the alert come at a certain time?

The aggregation feature will take every alert that has occurred over a period of time and send them together in one alert. You can use cron style syntax to send all alerts that have occurred since the last once by using

```
aggregation:
  schedule: '2 4 * * mon,fri'
```

## 9.8 I have lots of documents and it's really slow, how can I speed it up?

There are several ways to potentially speed up queries. If you are using `index: logstash-*`, Elasticsearch will query all shards, even if they do not possibly contain data with the correct timestamp. Instead, you can use Python time format strings and set `use_strftime_index`

```
index: logstash-%Y.%m
use_strftime_index: true
```

Another thing you could change is `buffer_time`. By default, ElastAlert 2 will query large overlapping windows in order to ensure that it does not miss any events, even if they are indexed in real time. In `config.yaml`, you can adjust `buffer_time` to a smaller number to only query the most recent few minutes.

```
buffer_time:
  minutes: 5
```

By default, ElastAlert 2 will download every document in full before processing them. Instead, you can have ElastAlert 2 simply get a count of the number of documents that have occurred in between each query. To do this, set `use_count_query: true`. This cannot be used if you use `query_key`, because ElastAlert 2 will not know the contents of each documents, just the total number of them. This also reduces the precision of alerts, because all events that occur between each query will be rounded to a single timestamp.

If you are using `query_key` (a single key, not multiple keys) you can use `use_terms_query`. This will make ElastAlert 2 perform a terms aggregation to get the counts for each value of a certain field. May not be compatible with all rule types.

## 9.9 Can I perform aggregations?

The only aggregation supported currently is a terms aggregation, by setting `use_terms_query`.

## 9.10 I'm not using @timestamp, what do I do?

You can use `timestamp_field` to change which field ElastAlert 2 will use as the timestamp. You can use `timestamp_type` to change it between ISO 8601 and unix timestamps. You must have some kind of timestamp for ElastAlert 2 to work. If your events are not in real time, you can use `query_delay` and `buffer_time` to adjust when ElastAlert 2 will look for documents.

## 9.11 I'm using flatline but I don't see any alerts

When using `type: flatline`, ElastAlert 2 must see at least one document before it will alert you that it has stopped seeing them.

## 9.12 How can I get a “resolve” event?

ElastAlert 2 does not currently support stateful alerts or resolve events. However, if you have a rule alerting you that a condition has occurred, such as a service being down, then you can create a second rule that will monitor the first rule, and alert you when the first rule ceases to trigger.

For example, assuming you already have a rule named “Service is offline” that’s working today, you can add a second rule as follows:

```
name: Service is back online
type: flatline
index: elasticsearch*
query_key: "rule_name"
filter:
- query:
    query_string:
      query: "rule_name:\"Service is offline\" AND matches:>0"
forget_keys: true
timeframe:
  minutes: 30
threshold: 1
```

This second rule will trigger after the timeframe of 30 minutes has elapsed with no further matches against the first rule.

## 9.13 Can I set a warning threshold?

Currently, the only way to set a warning threshold is by creating a second rule with a lower threshold.

## 9.14 Does it support Elastic Cloud's "Cloud ID"?

While Elastic Cloud is supported via the traditional URL connection method, connecting via Cloud ID is not currently supported.

## 9.15 I need to go through an http(s) proxy to connect to Elasticsearch. Does ElastAlert 2 support it?

Not supported.

## 9.16 About boolean value

You can use all lowercase letters or only uppercase letters at the beginning.

example

```
# OK
use_ssl: true
# OK
use_ssl: True
# OK
use_ssl: false
# OK
use_ssl: False
```

## 9.17 Is it possible to send an SNMP Trap with an alert notification?

- You need to additionally install `snmp snmptrapd` on the docker image. In other words, you need to modify the Dockerfile and recreate the Docker image with `docker build`.
- It is possible with the command `Alerter`.

example

```
name: "mariadb-error-log-warning"
type: "frequency"
index: "mariadb-*"
num_events: 1
timeframe:
minutes: 5
realert:
minutes: 1
filter:
```

(continues on next page)

(continued from previous page)

```

- query:
  query_string:
    query: "@log_name:mysql.error AND message:Warning"
alert:
- command
command: ["/usr/bin/snmptrap", "-IR", "-v", "2c", "-c", "public", "xxx.xxx.xxx.xxxxx:xxx",
  "netSnmp.99999", "netSnmp.99999.1", "s", "Hello, World"]
is_enabled: true
timestamp_field: "@timestamp"
timestamp_type: "iso"
use_strftime_index: false

```

## 9.18 Is Email Alerter compatible with Microsoft 365 (formerly Office 365)?

Not supported.

## 9.19 Does Email Alerter support the Google Gmail API?

Not supported.

## 9.20 Can Email Alerter send emails via the Gmail sending server?

It is possible. However, you need to turn on (enable) the item “Access to insecure apps” in the “Security” settings of your Google account.

## 9.21 Is it possible to send a JPEG image encoded as base64 in elasticsearch as an image attachment with an Email Alerter?

Yes, this is possible if the base64 encoded bytes are available in the matched document, as shown in the example below:

```

include: [base64field]
alert_text_args: [base64field]
email_format: "html"
alert_text_type: alert_text_only
alert_text: |
  <html>
  <body>
  <div>
    
  </div>
  </body>
  </html>

```

## 9.22 Does the alert notification destination support Alertmanager?

Now supported as of ElastAlert 2.2.3.

## 9.23 The `es_host` parameter seems to use only one host. Is it possible to specify multiple nodes?

There are two options:

1. Use haproxy in front of elasticsearch to support multiple hosts.
2. Use the new `es_hosts` parameter introduced in ElastAlert 2.2.3. See [Configuration](#).

## 9.24 Is there any plan to implement a REST API into this project?

No plan.

## 9.25 An error occurred when trying to create a blacklist rule that parses a file with more than 1024 lines.

This is the default limit for ElasticSearch. Specifying more than 1024 items in the blacklist will result in an error. This is a known issue. Perhaps White List can have similar issues. See the following issues on the original [yelp/elastalert](#) for more information.

Blacklist filter with 10.000+ terms is extremely slow.

Failed to parse query for blacklist rule when file contains more than 1024 entries.

## 9.26 ElastAlert 2 doesn't have a listening port?

ElastAlert 2 does not have a network API. There is no listening port, unless activating optional modules like Prometheus. You can monitor its activity by viewing the console output or Docker logs.

## 9.27 I've set `ssl_show_warn` but it doesn't seem to work.

Now supported as of ElastAlert 2.4.0.

## 9.28 How to write a query filter for phrases containing spaces?

To search for values containing spaces, or other special characters you will need to use escape characters. This is briefly mentioned at the bottom of the [Lucene Query Parser Syntax documentation]([https://lucene.apache.org/core/2\\_9\\_4/queryparsersyntax.html](https://lucene.apache.org/core/2_9_4/queryparsersyntax.html)) but does not go into extensive detail. Below are some examples to use in ElastAlert 2 rule filters.

Example 1 - Escaping double quotes within double quotes. Useful for embedded single quotes and double quotes in your search phrase:

```
filter:
- query:
  query_string:
    query: "\"Women's Clothing\""
```

Example 2 - Avoiding escaping altogether by enclosing double quotes within single quotes:

```
filter:
- query:
  query_string:
    query: '"Rabbia Al"'
```

## 9.29 Does ElastAlert 2 support Elasticsearch 8?

ElastAlert 2 supports Elasticsearch 8.

To upgrade an existing ElastAlert 2 installation to Elasticsearch 8 the following manual steps are required (note the important WARNING below):

- Shutdown ElastAlert 2.
- Delete the old `elastalert*` indices. See [Elasticsearch documentation](<https://www.elastic.co/guide/en/elasticsearch/reference/current/indices-delete-index.html>) for instructions on how to delete via the API, or use the Kibana Index Management interface.
- Upgrade the Elastic cluster to Elasticsearch 8 following the [Elastic 8 upgrade instructions](<https://elastic.co/guide/en/elastic-stack/8.0/upgrading-elastic-stack.html>).
- If NOT running ElastAlert 2 via Docker or Kubernetes, run `elastalert-create-index` to create the new indices. This is not needed when running via a container since the container always attempts to create the indices at startup, if they're not yet created.
- Restart ElastAlert 2.

**WARNING:** Failure to remove the old ElastAlert indices can result in a non-working Elasticsearch cluster. This is because the ElastAlert indices contain deprecated features and the Elasticsearch 8 upgrade logic is currently flawed and does not correctly handle this situation. The Elasticsearch GitHub repository contains [more information](<https://github.com/elastic/elasticsearch/issues/84199>) on this problem.

### 9.30 Support multiple sns\_topic\_arn in Alert Amazon SNS(Simple Notification Service)?

example

```
alert:
- sns:
  sns_topic_arn: "aws-topic1"
- sns:
  sns_topic_arn: "aws-topic2"
```

### 9.31 Support multiple telegram\_room\_id in Alert Telegram?

example

```
alert:
- telegram:
  telegram_room_id: "AAA"
- telegram:
  telegram_room_id: "BBB"
telegram_bot_token: "XXX"
```

### 9.32 Is it possible to set a timeout for connecting to and reading from es\_host ?

default is 20.

example

```
es_conn_timeout: 60
```

### 9.33 Is it possible to stop disabling rules for ElastAlert 2?

default is true.

example

```
disable_rules_on_error: false
```

## 9.34 Is there an introductory article about elastalet2?

Yelp, the developer of the original elastalet, has the following article on its blog.

[ElastAlert: Alerting At Scale With Elasticsearch, Part 1.](#)

[ElastAlert: Alerting At Scale With Elasticsearch, Part 2.](#)

## INDICES AND TABLES

- `genindex`
- `modindex`
- `search`
